This Project Guide is intended to provide the information necessary for the layout of a marine propulsion plant.

The information is to be considered as **preliminary**. It is intended for the project stage only and subject to modification in the interest of technical progress. The Project Guide provides the general technical data available at the date of issue.

It should be noted that all figures, values, measurements or information about performance stated in this project guide are **for guidance only** and should not be used for detailed design purposes or as a substitute for specific drawings and instructions prepared for such purposes.

**Data updates**
Data not finally calculated at the time of issue is marked ‘Available on request’. Such data may be made available at a later date, however, for a specific project the data can be requested. Pages and table entries marked ‘Not applicable’ represent an option, function or selection which is not valid.

The latest, most current version of the individual Project Guide sections are available on the Internet at: www.marine.man.eu → 'Two-Stroke'.

**Extent of Delivery**
The final and binding design and outlines are to be supplied by our licensee, the engine maker, see Chapter 20 of this Project Guide.

In order to facilitate negotiations between the yard, the engine maker and the customer, a set of ‘Extent of Delivery’ forms is available in which the basic and the optional executions are specified.

**Electronic versions**
This Project Guide book and the ‘Extent of Delivery’ forms are available on the Internet at: www.marine.man.eu → 'Two-Stroke', where they can be downloaded.

**Edition 0.5**
May 2014
All data provided in this document is non-binding. This data serves informational purposes only and is especially not guaranteed in any way.

Depending on the subsequent specific individual projects, the relevant data may be subject to changes and will be assessed and determined individually for each project. This will depend on the particular characteristics of each individual project, especially specific site and operational conditions.

If this document is delivered in another language than English and doubts arise concerning the translation, the English text shall prevail.

Engine Design
The Fuel Optimised MC-C Tier II Engine

Whether the freight rates rise or fall, an attractive payback time for newbuildings starts with low investment cost. Once in operation, the ease and flexibility in assigning engineers to operate the engine plant are together with low consumption rates of fuels, lubes, parts and service among the important functional issues which contribute to the cost benefit. The MAN B&W MC-C engine meets both requirements.

The world market-leading two-stroke MC/MC-C engine programme from MAN Diesel has evolved since the early 1980s to embrace bore sizes from 260 mm to 980 mm for propelling ocean-going ships of all types and sizes. Also land-based applications (power plants mainly) have found the MC/MC-C engine types attractive.

The MC-C engine features chain driven camshaft, camshaft controlled fuel injection timing and exhaust valve opening as well as a conventional fuel oil pumps, all well-known and proven technology familiar to marine engineers all over the world.

To conclude, the MAN B&W MC-C engine combines classic virtues of commonly known, well-proven technology continuously upgraded and up-rated to suit the requirements to modern prime movers. Consequently, our latest cutting edge design and manufacturing features are built into each component.

Concept of the MC-C engine

The engine concept is based on a mechanical camshaft system for activation of the fuel injection and the exhaust valves. The engine is provided with a pneumatic/electric manoeuvring system and the engine speed is controlled by an electronic/hydraulic type governor.

Each cylinder is equipped with its own fuel injection pump, which consists of a simple plunger activated by the fuel cam directly. The optimal combination of NOx and SFOC (Specific Fuel Oil Consumption) is achieved by means of the Variable Injection Timing (VIT) incorporated in the fuel pumps (applicable for MC-C engines type 90-46 only).

The cam controlled exhaust valve is opened hydraulically and closed by means of an air spring.

Lubrication is either by means of a uni-lube oil system serving both crankshaft, chain drive, piston cooling and camshaft or a combination of a main lubricating oil system and a separate camshaft lube oil system.

Cylinder lubrication is accomplished by electronically controlled Alpha lubricators, securing a low lube oil consumption, or timed mechanical lubricators alternatively.

The starting valves are opened pneumatically by control air from the starting air distributor(s) and closed by a spring.

Engine design and IMO regulation compliance

The MC-C engine is the shorter, more compact version of the MC engine. It is well suited wherever a small engine room is requested, for instance in container vessels.

For MAN B&W MC-C-TII designated engines, the design and performance parameters have been upgraded and optimised to comply with the International Maritime Organisation (IMO) Tier II emission regulations.

The potential derating and part load SFOC figures for the Tier II engines have also been updated.

For engines built to comply with IMO Tier I emission regulations, please refer to the Marine Engine IMO Tier I Project Guide.

The main features of the MC engine are described in the following pages.
**Tier II fuel optimisation**

NO\(_x\) regulations place a limit on the SFOC on two-stroke engines. In general, NO\(_x\) emissions will increase if SFOC is decreased and vice versa. In the standard configuration, MAN B&W engines are optimised close to the IMO NO\(_x\) limit and, therefore, NO\(_x\) emissions may not be further increased.

The IMO NO\(_x\) limit is given as a weighted average of the NO\(_x\) emission at 25, 50, 75 and 100% load. This relationship can be utilised to tilt the SFOC profile over the load range. This means that SFOC can be reduced at part load or low load at the expense of a higher SFOC in the high-load range without exceeding the IMO NO\(_x\) limit.

Optimisation of SFOC in the part-load (50-85%) or low-load (25-70%) range requires selection of a tuning method:

- **VT**: Variable Turbine Area
- **EGB**: Exhaust Gas Bypass

Each tuning method makes it possible to optimise the fuel consumption when normally operating at low loads, while maintaining the possibility of operating at high load when needed.

The tuning methods are available for all SMCR in the specific engine layout diagram but they cannot be combined. The specific SFOC reduction potential of each tuning method together with full rated (L\(_1\)/L\(_3\)) and maximum derated (L\(_2\)/L\(_4\)) is shown in Section 1.03.

For engine types 40 and smaller, as well as for larger types with conventional turbochargers, only high-load optimisation is applicable.

In general, data in this project guide is based on high-load optimisation unless explicitly noted. For part- and low-load optimisation, calculations can be made in the CEAS application described in Section 20.02.

**Application of MC-C engines**

For further information about the application of MC-C engines based on ship particulars and power demand, please refer to our publications titled:

*Propulsion Trends in Container Vessels*

*Propulsion Trends in Bulk Carriers*

*Propulsion Trends in Small Tankers*

The publications are available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'.

**Fig 1.03.01: Power, speed and fuel**
Engine Power Range and Fuel Oil Consumption

Engine Power

The following tables contain data regarding the power, speed and specific fuel oil consumption of the engine.

Engine power is specified in kW for each cylinder number and layout points L₁, L₂, L₃ and L₄.

Discrepancies between kW and metric horsepower (1 BHP = 75 kpm/s = 0.7355 kW) are a consequence of the rounding off of the BHP values.

L₁ designates nominal maximum continuous rating (nominal MCR), at 100% engine power and 100% engine speed.

L₂, L₃ and L₄ designate layout points at the other three corners of the layout area, chosen for easy reference.

![Power vs Speed Diagram](image)

**Fig. 1.04.01: Layout diagram for engine power and speed**

Overload corresponds to 110% of the power at MCR, and may be permitted for a limited period of one hour every 12 hours.

The engine power figures given in the tables remain valid up to tropical conditions at sea level as stated in IACS M28 (1978), i.e.:

- Blower inlet temperature: 45 °C
- Blower inlet pressure: 1,000 mbar
- Seawater temperature: 32 °C
- Relative humidity: 60%

Specific Fuel Oil Consumption (SFOC)

The figures given in this folder represent the values obtained when the engine and turbocharger are matched with a view to obtaining the lowest possible SFOC values while also fulfilling the IMO NOX Tier II emission limitations.

Stricter emission limits can be met on request, using proven technologies.

The SFOC figures are given in g/kWh with a tolerance of 5% (at 100% SMCR) and are based on the use of fuel with a lower calorific value of 42,700 kJ/kg (~10,200 kcal/kg) at ISO conditions:

- Ambient air pressure: 1,000 mbar
- Ambient air temperature: 25 °C
- Cooling water temperature: 25 °C
- Blower inlet temperature: 45 °C
- Blower inlet pressure: 1,000 mbar
- Seawater temperature: 32 °C
- Relative humidity: 60%

Although the engine will develop the power specified up to tropical ambient conditions, specific fuel oil consumption varies with ambient conditions and fuel oil lower calorific value. For calculation of these changes, see Chapter 2.

**Lubricating oil data**

The cylinder oil consumption figures stated in the tables are valid under normal conditions.

During running-in periods and under special conditions, feed rates of up to 1.5 times the stated values should be used.
Performance Curves

Updated engine and capacities data is available from the CEAS program on www.marine.man.eu → 'Two-Stroke' → 'CEAS Engine Calculations'.
MC-C Engine Description

Please note that engines built by our licensees are in accordance with MAN Diesel & Turbo drawings and standards but, in certain cases, some local standards may be applied; however, all spare parts are interchangeable with MAN Diesel & Turbo designed parts.

Some components may differ from MAN Diesel & Turbo’s design because of local production facilities or the application of local standard components.

In the following, reference is made to the item numbers specified in the ‘Extent of Delivery’ (EoD) forms, both for the ‘Basic’ delivery extent and for some ‘Options’.

Bedplate and Main Bearing

The bedplate is made with the thrust bearing in the aft end of the engine. The bedplate consists of high, welded, longitudinal girders and welded cross girders with cast steel bearing supports.

For fitting to the engine seating in the ship, long, elastic holding-down bolts, and hydraulic tightening tools are used.

The bedplate is made without taper for engines mounted on epoxy chocks.

The oil pan, which is made of steel plate and is welded to the bedplate, collects the return oil from the forced lubricating and cooling oil system. The oil outlets from the oil pan are vertical as standard and provided with gratings.

Horizontal outlets at both ends can be arranged for some cylinder numbers, however, this must be confirmed by the engine builder.

The main bearings consist of thin walled steel shells lined with bearing metal. The main bearing bottom shell can be rotated out and in by means of special tools in combination with hydraulic tools for lifting the crankshaft. The shells are kept in position by a bearing cap.

Frame Box

The frame box is of triangular plate welded or rib design. On the exhaust side, it is provided with relief valves for each cylinder while, on the manoeuvring side, it is provided with a large hinged door for each cylinder. The crosshead guides are welded onto the frame box.

The frame box is bolted to the bedplate. The bedplate, frame box and cylinder frame are tightened together by stay bolts.

Cylinder Frame and Stuffing Box

The cylinder frame is either welded or cast and is provided with access covers for cleaning the scavenge air space, if required, and for inspection of scavenge ports and piston rings from the manoeuvring side. Together with the cylinder liner, it forms the scavenge air space.

The cylinder frame is fitted with pipes for the piston cooling oil inlet. The scavenge air receiver, turbocharger, air cooler box, lubricators and gallery brackets are located on the cylinder frame. At the bottom of the cylinder frame there is a piston rod stuffing box, provided with sealing rings for scavenge air. Oil scraper rings in the stuffing box prevent crankcase oil from coming up into the scavenge air space.

Drains from the scavenge air space and the piston rod stuffing box are located at the bottom of the cylinder frame.

Cylinder Liner

The cylinder liner is made of alloyed cast iron and is suspended in the cylinder frame with a low-situated flange. The top of the cylinder liner is fitted with a cooling jacket. The cylinder liner has scavenge ports and drilled holes for cylinder lubrication.
Cylinder liners prepared for installation of temperature sensors is basic execution on engines type 90 while an option on all other engines.

**Cylinder Cover**

The cylinder cover is of forged steel, made in one piece, and has bores for cooling water. It has a central bore for the exhaust valve, and bores for the fuel valves, a starting valve and an indicator valve.

The cylinder cover is attached to the cylinder frame with studs and nuts tightened with hydraulic jacks.

**Crankshaft**

The crankshaft is mainly of the semi-built type, made from forged or cast steel throws. In engines with 9 cylinders or more the crankshaft is supplied in two parts.

At the aft end, the crankshaft is provided with the collar for the thrust bearing, and the flange for the turning wheel and for the coupling bolts to an intermediate shaft.

At the front end, the crankshaft is fitted with the collar for the axial vibration damper and a flange for the fitting of a tuning wheel. The flange can also be used for a Power Take Off, if so desired.

Coupling bolts and nuts for joining the crankshaft together with the intermediate shaft are not normally supplied.

**Thrust Bearing**

The propeller thrust is transferred through the thrust collar, the segments, and the bedplate, to the end chocks and engine seating, and thus to the ship's hull.

The thrust bearing is located in the aft end of the engine. The thrust bearing is of the B&W-Michell type, and consists primarily of a thrust collar on the crankshaft, a bearing support, and segments of steel lined with white metal.

Engines type 60 and larger with 9 cylinders or more will be specified with the 360º degree type thrust bearing, while the 240º degree type is used in all other engines. MAN Diesel & Turbo's flexible thrust cam design is used for the thrust collar on a range of engine types.

The thrust shaft is an integrated part of the crankshaft and lubricated by the engine's lubricating oil system.

**Turning Gear and Turning Wheel**

The turning wheel is fitted to the thrust shaft and driven by a pinion on the terminal shaft of the turning gear, which is mounted on the bedplate. The turning gear is driven by an electric motor with built-in gear with brake.

A blocking device prevents the main engine from starting when the turning gear is engaged. Engagement and disengagement of the turning gear is effected manually by an axial movement of the pinion.

The control device for the turning gear, consisting of starter and manual control box, can be ordered as an option.

**Axial Vibration Damper**

The engine is fitted with an axial vibration damper, mounted on the fore end of the crankshaft. The damper consists of a piston and a split-type housing located forward of the foremost main bearing.

The piston is made as an integrated collar on the main crank journal, and the housing is fixed to the main bearing support.

For functional check of the vibration damper, a mechanical guide is fitted, while an electronic vibration monitor can be supplied as an option.
Tuning Wheel/Torsional Vibration Damper

A tuning wheel or torsional vibration damper may have to be ordered separately, depending on the final torsional vibration calculations.

Connecting Rod

The connecting rod is made of forged steel or cast and provided with bearing caps for the crosshead and crankpin bearings.

The crosshead and crankpin bearing caps are secured to the connecting rod with studs and nuts tightened by means of hydraulic jacks.

The crosshead bearing consists of a set of thin-walled steel shells, lined with bearing metal. The crosshead bearing cap is in one piece, with an angular cut-out for the piston rod.

The crankpin bearing is provided with thin-walled steel shells, lined with bearing metal. Lube oil is supplied through ducts in the crosshead and connecting rod.

Piston

The piston consists of a piston crown and piston skirt. The piston crown is made of heat-resistant steel. A piston cleaning ring located in the very top of the cylinder liner scrapes off excessive ash and carbon formations on the piston topland.

The piston has four ring grooves which are hard-chrome plated on both the upper and lower surfaces of the grooves. The uppermost piston ring is of the Controlled Pressure Relief type (CPR), whereas the other three piston rings all have an oblique cut. All four rings are alu-coated on the outer surface for running-in.

The piston skirt is made of cast iron with a bronze band or Mo coating.

Piston Rod

The piston rod is of forged steel and is surface-hardened on the running surface for the stuffing box. The piston rod is connected to the crosshead with four bolts. The piston rod has a central bore which, in conjunction with a cooling oil pipe, forms the inlet and outlet for cooling oil.

Crosshead

The crosshead is of forged steel and is provided with cast steel guide shoes of low-friction design with white metal on the running surface.

The telescopic pipe for oil inlet and the pipe for oil outlet are mounted on the guide shoes.

Scavenge Air System

The air intake to the turbocharger takes place directly from the engine room through the turbocharger intake silencer. From the turbocharger, the air is led via the charging air pipe, air cooler and scavenge air receiver to the scavenge ports of the cylinder liners, see Chapter 14. The scavenge air receiver on engines type 65 is of the D-shape design.

Scavenge Air Cooler

For each turbocharger a scavenge air cooler of the mono-block type is fitted. The cooler is designed as a central cooling system cooled by freshwater of maximum 4.5 bar working pressure. Alternatively, a seawater cooling system with up to 2.0 - 2.5 bar working pressure can be chosen.

The scavenge air cooler is so designed that the difference between the scavenge air temperature and the water inlet temperature at specified MCR can be kept at about 12 °C.
**Auxiliary Blower**

The engine is provided with electrically-driven scavenge air blowers. The suction side of the blowers is connected to the scavenge air space after the air cooler.

Between the air cooler and the scavenge air receiver, non-return valves are fitted which automatically close when the auxiliary blowers supply the air.

The auxiliary blowers will start operating consecutively before the engine is started in order to ensure sufficient scavenge air pressure to obtain a safe start.

Further information is given in Chapter 14.

**Exhaust Gas System**

From the exhaust valves, exhaust gas is led to the exhaust gas receiver where the fluctuating pressure from the individual cylinders is equalised, and the total volume of gas is led further on to the turbocharger(s). After the turbocharger(s), the gas is led to the external exhaust pipe system.

Compensators are fitted between the exhaust valves and the receiver, and between the receiver and the turbocharger(s).

The exhaust gas receiver and exhaust pipes are provided with insulation, covered by galvanised steel plating.

A protective grating is installed between the exhaust gas receiver and the turbocharger.

**Exhaust Turbocharger**

The engines can be fitted with either MAN, ABB or MHI turbochargers. As an option, MAN TCA turbochargers can be delivered with variable nozzle technology that reduces the fuel consumption at part load by controlling the scavenge air pressure.

The turbocharger selection is described in Chapter 3, and the exhaust gas system in Chapter 15.

**Camshaft and Cams**

The camshaft consists of a number of sections each having a shaft piece with exhaust cams, fuel cams, coupling parts and indicator drive cams.

The exhaust cams and fuel cams are made of steel, with a hardened roller race, and are shrunk onto the shaft. They can be adjusted and dismantled hydraulically.

The cam for the indicator drive can be adjusted mechanically. The coupling parts are shrunk onto the shaft and can be adjusted and dismantled hydraulically.

The camshaft bearings consist of one lower half-shell fitted in a bearing support. The camshaft is lubricated by the main lubricating oil system.

**Chain Drive**

The camshaft is driven from the crankshaft by a chain drive, which is kept running tight by a manually adjusted chain tightener. The long free lengths of chain are supported by rubber-clad guidebars and the chain is lubricated through oil spray pipes fitted at the chain wheels and guidebars.

The mechanical cylinder lubricators, if fitted, are driven from the camshaft by a separate chain.

**Indicator Drive**

As separate options, the engine can be supplied with either an indicator drive, a mechanical indicator system, or the so-called PMI system, a pressure analyser system, described in section 18.02.

The indicator drive consists of a cam fitted on the camshaft and a spring-loaded spindle with a roller which moves up and down in accordance with the movement of the piston within the engine cylinder. At the top, the spindle has an eye to which the indicator cord is fastened after the indicator has been installed on the indicator valve.
Governor

The engine is to be provided with a governor of a make approved by MAN Diesel & Turbo, controlling the fuel pump through an actuator. The governor must meet the ISO 3046 standard, part IV, 1997.

The speed setting of the actuator is determined by an electronic signal from the electronic governor based on the position of the main engine regulating handle. The actuator is connected to the fuel regulating shaft by means of a mechanical linkage. Alternatively for engines type 46 without PTO, a mechanical/hydraulic Woodward governor for pneumatic speed setting could be provided.

Fuel Oil Pump and Fuel Oil High Pressure Pipes

The engine is provided with one fuel pump for each cylinder. The fuel pump consists of a pump housing of nodular cast iron, a centrally placed pump barrel, and a plunger of nitrated steel. In order to prevent fuel oil from mixing with the lubricating oil, the pump actuator is provided with a sealing arrangement.

The pump is placed on the roller guide housing and activated by the fuel cam. The volume injected is controlled by turning the plunger by means of a toothed rack connected to the regulating shaft.

For optimal combination of NOx and SFOC, the fuel pumps incorporate Variable Injection Timing (VIT). The VIT uses the governor fuel setting as the controlling parameter.

The fuel oil pump is provided with a puncture valve, which prevents high pressure from building up during normal stopping and shut down.

The roller guide housing is provided with a semi-automatic (optional on engines type 70, 60 and 50) lifting device which, during rotation of the engine, can lift the roller guide free of the cam. On 46 types, a separate tool is used to lift the roller guide.

The fuel oil high-pressure pipes are either double-walled or of the hose type.

Further information is given in Section 7.01.

Fuel Valves and Starting Air Valve

Each cylinder cover is equipped with two or three fuel valves, starting air valve (SAV), and indicator valve.

The opening of the fuel valves is controlled by the high fuel oil pressure created by the fuel oil pump, and the valves are closed by a spring. The fuel valves are cooled by the fuel.

An automatic vent slide allows circulation of fuel oil through the valve and high pressure pipes when the engine is stopped. The vent slide also prevents the compression chamber from being filled up with fuel oil in the event that the valve spindle sticks. Oil from the vent slide and other drains is led away in a closed system.

The starting air valve is opened by control air from the starting air distributor and is closed by a spring. The control air supply is regulated so that the starting valves deliver starting air to the cylinders in the correct firing order.

Starting Air System

The starting air system comprises a main starting valve, one or two starting air distributors (one only on 46 types) and a non-return valve, a bursting disc for the branch pipe and a starting valve on each cylinder. The main starting valve is connected with the manoeuvring system, which controls the start of the engine.

A slow turning valve can be ordered as an option. The slow-turning function is actuated manually from the manoeuvring console.

The starting air system is described in detail in Section 13.01.
Exhaust Valve

The exhaust valve consists of the valve housing and the valve spindle. The valve housing is made of cast iron and is arranged for water cooling. The housing is provided with a water cooled bottom piece of steel with a flame-hardened seat of the W-seat design.

The exhaust valve spindle is a DuraSpindle or made of Nimonic. The housing is provided with a spindle guide.

The exhaust valve is tightened to the cylinder cover with studs and nuts. It is opened hydraulically and closed by means of air pressure. The hydraulic system consists of a piston actuator placed on the roller guide housing, a high-pressure pipe, and a working cylinder on the exhaust valve. The piston actuator is activated by a cam on the camshaft.

In operation, the valve spindle slowly rotates, driven by the exhaust gas acting on small vanes fixed to the spindle.

Sealing of the exhaust valve spindle guide is provided by means of Controlled Oil Level (COL), an oil bath in the bottom of the air cylinder, above the sealing ring. This oil bath lubricates the exhaust valve spindle guide and sealing ring as well.

Cylinder Lubrication

The cylinder lubrication system can be of either the electronic MAN B&W Alpha cylinder lubrication system or a mechanical type.

The cylinder lubrication systems are described in detail in Chapter 9.

Manoeuvring System

The engine is provided with a pneumatic/electric manoeuvring and fuel oil regulating system. The system transmits orders from the separate manoeuvring consoles to the engine.

The regulating system makes it possible to start, stop, reverse the engine and control the engine speed. The speed control on the manoeuvring console gives a speed-setting signal to the governor, dependent on the desired number of revolutions.

At shut-down, the fuel injection is stopped by the puncture valves in the fuel pumps being activated, independently of the speed control. At reversing, the displaceable rollers in the driving mechanism for the fuel pumps are moved to the 'Aft' position by air cylinders controlled by the starting air distributor.

The engine is provided with an engine side mounted console and instrument panel.

Reversing

On reversible engines (with Fixed Pitch Propellers mainly), reversing of the engine is performed by means of an angular displaceable roller in the driving mechanism for the fuel pump of each engine cylinder. The reversing mechanism is activated and controlled by compressed air supplied to the engine.

The exhaust valve gear is not to be reversed.

Gallery Arrangement

The engine is provided with gallery brackets, stanchions, railings, platforms (exclusive of ladders). The brackets are placed at such a height as to provide the best possible overhauling and inspection conditions.

The engine is prepared for top bracings on the exhaust side, or on the manoeuvring side.
Piping Arrangements

The engine is delivered with piping arrangements for:

- Fuel oil
- Heating of fuel oil pipes
- Lubricating oil, piston cooling oil and camshaft lubrication
- Cylinder lubricating oil
- Cooling water to scavenge air cooler
- Jacket and turbocharger cooling water
- Cleaning of scavenge air cooler
- Cleaning of turbocharger
- Fire extinguishing in scavenge air space
- Starting air
- Control air
- Safety air
- Oil mist detector (required only for make Schaller Automation)
- Various drain pipes.

All piping arrangements are made of steel piping, except the control air, safety air and steam heating of fuel pipes, which are made of copper.

The pipes are provided with sockets for local instruments, alarm and safety equipment and, furthermore, with a number of sockets for supplementary signal equipment. Chapter 18 deals with the instrumentation.
Engine Cross Section of S46MC-C7/8

Fig.: 1.07.01: Engine cross section
Engine Layout and Load Diagrams, SFOC
Engine Layout and Load Diagrams

Introduction

The effective power ‘P’ of a diesel engine is proportional to the mean effective pressure $p_e$ and engine speed ‘n’, i.e. when using ‘c’ as a constant:

$$P = c \times p_e \times n$$

so, for constant mep, the power is proportional to the speed:

$$P = c \times n^i$$

When running with a Fixed Pitch Propeller (FPP), the power may be expressed according to the propeller law as:

$$P = c \times n^3$$

Thus, for the above examples, the power P may be expressed as a power function of the speed ‘n’ to the power of ‘i’, i.e.:

$$P = c \times n^i$$

Fig. 2.01.01 shows the relationship for the linear functions, $y = ax + b$, using linear scales.

The power functions $P = c \times n^i$ will be linear functions when using logarithmic scales:

$$\log (P) = i \times \log (n) + \log (c)$$

Thus, propeller curves will be parallel to lines having the inclination $i = 3$, and lines with constant mep will be parallel to lines with the inclination $i = 1$.

Therefore, in the Layout Diagrams and Load Diagrams for diesel engines, logarithmic scales are used, giving simple diagrams with straight lines.

Propulsion and Engine Running Points

Propeller curve

The relation between power and propeller speed for a fixed pitch propeller is as mentioned above described by means of the propeller law, i.e. the third power curve:

$$P = c \times n^3$$

in which:

P = engine power for propulsion
n = propeller speed
c = constant

Propeller design point

Normally, estimates of the necessary propeller power and speed are based on theoretical calculations for loaded ship, and often experimental tank tests, both assuming optimum operating conditions, i.e. a clean hull and good weather. The combination of speed and power obtained may be called the ship’s propeller design point (PD),
placed on the light running propeller curve 6. See below figure. On the other hand, some shipyards, and/or propeller manufacturers sometimes use a propeller design point (PD) that incorporates all or part of the so-called sea margin described below.

the so-called sea margin, which is traditionally about 15% of the propeller design (PD) power.

**Engine layout (heavy propeller)**

When determining the necessary engine layout speed that considers the influence of a heavy running propeller for operating at high extra ship resistance, it is (compared to line 6) recommended to choose a heavier propeller line 2. The propeller curve for clean hull and calm weather line 6 may then be said to represent a ‘light running’ (LR) propeller.

Compared to the heavy engine layout line 2, we recommend using a light running of 3.0-7.0% for design of the propeller.

**Engine margin**

Besides the sea margin, a so-called ‘engine margin’ of some 10% or 15% is frequently added. The corresponding point is called the ‘specified MCR for propulsion’ (MP), and refers to the fact that the power for point SP is 10% or 15% lower than for point MP.

Point MP is identical to the engine’s specified MCR point (M) unless a main engine driven shaft generator is installed. In such a case, the extra power demand of the shaft generator must also be considered.

**Constant ship speed lines**

The constant ship speed lines \( \propto \), are shown at the very top of the figure. They indicate the power required at various propeller speeds in order to keep the same ship speed. It is assumed that, for each ship speed, the optimum propeller diameter is used, taking into consideration the total propulsion efficiency. See definition of \( \propto \) in Section 2.02.

**Note:**

Light/heavy running, fouling and sea margin are overlapping terms. Light/heavy running of the propeller refers to hull and propeller deterioration and heavy weather, whereas sea margin i.e. extra power to the propeller, refers to the influence of the wind and the sea. However, the degree of light running must be decided upon experience from the actual trade and hull design of the vessel.
Propeller diameter and pitch, influence on the optimum propeller speed

In general, the larger the propeller diameter $D$, the lower is the optimum propeller speed and the kW required for a certain design draught and ship speed, see curve D in the figure below.

The maximum possible propeller diameter depends on the given design draught of the ship, and the clearance needed between the propeller and the aft body hull and the keel.

The example shown in the figure is an 80,000 dwt crude oil tanker with a design draught of 12.2 m and a design speed of 14.5 knots.

When the optimum propeller diameter $D$ is increased from 6.6 m to 7.2 m, the power demand is reduced from about 9,290 kW to 8,820 kW, and the optimum propeller speed is reduced from 120 r/min to 100 r/min, corresponding to the constant ship speed coefficient $\alpha = 0.28$ (see definition of $\alpha$ in Section 2.02, page 2).

Once an optimum propeller diameter of maximum 7.2 m has been chosen, the corresponding optimum pitch in this point is given for the design speed of 14.5 knots, i.e. $P/D = 0.70$.

However, if the optimum propeller speed of 100 r/min does not suit the preferred / selected main engine speed, a change of pitch away from optimum will only cause a relatively small extra power demand, keeping the same maximum propeller diameter:

• going from 100 to 110 r/min ($P/D = 0.62$) requires 8,900 kW i.e. an extra power demand of 80 kW.

• going from 100 to 91 r/min ($P/D = 0.81$) requires 8,900 kW i.e. an extra power demand of 80 kW.

In both cases the extra power demand is only of 0.9%, and the corresponding ‘equal speed curves’ are $\alpha = +0.1$ and $\alpha = -0.1$, respectively, so there is a certain interval of propeller speeds in which the ‘power penalty’ is very limited.

**Fig. 2.02.01: Influence of diameter and pitch on propeller design**
Constant ship speed lines

The constant ship speed lines $\propto$, are shown at the very top of Fig. 2.02.02. These lines indicate the power required at various propeller speeds to keep the same ship speed provided that the optimum propeller diameter with an optimum pitch diameter ratio is used at any given speed, taking into consideration the total propulsion efficiency.

Normally, the following relation between necessary power and propeller speed can be assumed:

$$P_2 = P_1 \times \left(\frac{n_2}{n_1}\right)^\propto$$

where:

$P =$ Propulsion power

$n =$ Propeller speed, and

$\propto =$ the constant ship speed coefficient.

For any combination of power and speed, each point on lines parallel to the ship speed lines gives the same ship speed.

When such a constant ship speed line is drawn into the layout diagram through a specified propulsion MCR point 'MP1', selected in the layout area and parallel to one of the $\propto$-lines, another specified propulsion MCR point 'MP2' upon this line can be chosen to give the ship the same speed for the new combination of engine power and speed.

Fig. 2.02.02 shows an example of the required power speed point MP1, through which a constant ship speed curve $\propto = 0.25$ is drawn, obtaining point MP2 with a lower engine power and a lower engine speed but achieving the same ship speed.

Provided the optimum pitch/diameter ratio is used for a given propeller diameter the following data applies when changing the propeller diameter:

for general cargo, bulk carriers and tankers $\propto = 0.25 - 0.30$

and for reefers and container vessels $\propto = 0.15 - 0.25$

When changing the propeller speed by changing the pitch diameter ratio, the $\propto$ constant will be different, see above.

Fig. 2.03.01 Layout diagram sizes
Engine Layout and Load Diagram

Engine Layout Diagram

An engine's layout diagram is limited by two constant mean effective pressure (mep) lines \( L_1 - L_3 \) and \( L_2 - L_4 \), and by two constant engine speed lines \( L_1 - L_2 \) and \( L_3 - L_4 \). The \( L_0 \) point refers to the engine's nominal maximum continuous rating, see Fig. 2.04.01.

Within the layout area there is full freedom to select the engine's specified SMCR point \( M \) which suits the demand for propeller power and speed for the ship.

On the horizontal axis the engine speed and on the vertical axis the engine power are shown on percentage scales. The scales are logarithmic which means that, in this diagram, power function curves like propeller curves (3rd power), constant mean effective pressure curves (1st power) and constant ship speed curves (0.15 to 0.30 power) are straight lines.

Specified maximum continuous rating (M)

Based on the propulsion and engine running points, as previously found, the layout diagram of a relevant main engine may be drawn-in. The SMCR point \( M \) must be inside the limitation lines of the layout diagram; if it is not, the propeller speed will have to be changed or another main engine type must be chosen. The selected SMCR has an influence on the turbocharger and its matching and the compression ratio.

For ME and ME-C/-GI engines, the timing of the fuel injection and the exhaust valve activation are electronically optimised over a wide operating range of the engine.

For ME-B engines, only the fuel injection (and not the exhaust valve activation) is electronically controlled over a wide operating range of the engine.

For a standard high-load optimised engine, the lowest specific fuel oil consumption for the ME and ME-C engines is obtained at 70% and for MC/MC-C/ME-B engines at 80% of the SMCR point \( M \).

For ME-C-GI engines operating on LNG, a further SFOC reduction can be obtained.

Continuous service rating (S)

The continuous service rating is the power needed in service – including the specified sea margin and heavy/light running factor of the propeller – at which the engine is to operate, and point \( S \) is identical to the service propulsion point (SP) unless a main engine driven shaft generator is installed.

For ME and ME-C/-GI engines, the lowest specific fuel oil consumption for the ME and ME-C engines is obtained at 70% and for MC/MC-C/ME-B engines at 80% of the SMCR point \( M \).

For ME-C-GI engines operating on LNG, a further SFOC reduction can be obtained.

For ME-B engines, only the fuel injection (and not the exhaust valve activation) is electronically controlled over a wide operating range of the engine.

For a standard high-load optimised engine, the lowest specific fuel oil consumption for the ME and ME-C engines is obtained at 70% and for MC/MC-C/ME-B engines at 80% of the SMCR point \( M \).

For ME-C-GI engines operating on LNG, a further SFOC reduction can be obtained.

For ME-B engines, only the fuel injection (and not the exhaust valve activation) is electronically controlled over a wide operating range of the engine.
Definitions

The engine's load diagram, see Fig. 2.04.02, defines the power and speed limits for continuous as well as overload operation of an installed engine having a specified MCR point M that confirms the ship's specification.

The service points of the installed engine incorporate the engine power required for ship propulsion and shaft generator, if installed.

Operating curves and limits for continuous operation

The continuous service range is limited by four lines: 4, 5, 7 and 3 (9), see Fig. 2.04.02. The propeller curves, line 1, 2 and 6 in the load diagram are also described below.

Line 1:
Propeller curve through specified MCR (M), engine layout curve.

Line 2:
Propeller curve, fouled hull and heavy weather – heavy running.

Line 3 and line 9:
Line 3 represents the maximum acceptable speed for continuous operation, i.e. 105% of M.

During trial conditions the maximum speed may be extended to 107% of M, see line 9.

The above limits may in general be extended to 105% and during trial conditions to 107% of the nominal L1 speed of the engine, provided the torsional vibration conditions permit.

The overspeed set-point is 109% of the speed in M, however, it may be moved to 109% of the nominal speed in L, provided that torsional vibration conditions permit.

Running at low load above 100% of the nominal L1 speed of the engine is, however, to be avoided for extended periods. Only plants with controllable pitch propellers can reach this light running area.

Line 4:
Represents the limit at which an ample air supply is available for combustion and imposes a limitation on the maximum combination of torque and speed.
Recommendation

Continuous operation without limitations is allowed only within the area limited by lines 4, 5, 7 and 3 of the load diagram, except on low load operation for CP propeller plants mentioned in the previous section.

The area between lines 4 and 1 is available for operation in shallow waters, heavy weather and during acceleration, i.e. for non-steady operation without any strict time limitation.

After some time in operation, the ship's hull and propeller will be fouled, resulting in heavier running of the propeller, i.e. the propeller curve will move to the left from line 6 towards line 2, and extra power is required for propulsion in order to keep the ship's speed.

In calm weather conditions, the extent of heavy running of the propeller will indicate the need for cleaning the hull and possibly polishing the propeller.

Once the specified MCR has been chosen, the capacities of the auxiliary equipment will be adapted to the specified MCR, and the turbocharger specification and the compression ratio will be selected.

If the specified MCR is to be increased later on, this may involve a change of the pump and cooler capacities, change of the fuel valve nozzles, adjusting of the cylinder liner cooling, as well as rematching of the turbocharger or even a change to a larger size of turbocharger. In some cases it can also require larger dimensions of the piping systems.

It is therefore of utmost importance to consider, already at the project stage, if the specification should be prepared for a later power increase. This is to be indicated in the Extent of Delivery.

Line 5:
Represents the maximum mean effective pressure level (mep), which can be accepted for continuous operation.

Line 6:
Propeller curve, clean hull and calm weather – light running, used for propeller layout/design.

Line 7:
Represents the maximum power for continuous operation.

Limits for overload operation

The overload service range is limited as follows:

Line 8:
Represents the overload operation limitations.

The area between lines 4, 5, 7 and the heavy dashed line 8 is available for overload running for limited periods only (1 hour per 12 hours).

Line 9:
Speed limit at sea trial.

Limits for low load running

As the fuel injection for ME engines is automatically controlled over the entire power range, the engine is able to operate down to around 15-20% of the nominal L₁ speed, whereas for MC/MC-C engines it is around 20-25% (electronic governor).
Extended load diagram for ships operating in extreme heavy running conditions

When a ship with fixed pitch propeller is operating in normal sea service, it will in general be operating in the hatched area around the design propeller curve 6, as shown on the standard load diagram in Fig. 2.04.02.

Sometimes, when operating in heavy weather, the fixed pitch propeller performance will be more heavy running, i.e. for equal power absorption of the propeller, the propeller speed will be lower and the propeller curve will move to the left.

As the low speed main engines are directly coupled to the propeller, the engine has to follow the propeller performance, i.e. also in heavy running propeller situations. For this type of operation, there is normally enough margin in the load area between line 6 and the normal torque/speed limitation line 4, see Fig. 2.04.02. To the left of line 4 in torque-rich operation, the engine will lack air from the turbocharger to the combustion process, i.e. the heat load limits may be exceeded and bearing loads might also become too high.

For some special ships and operating conditions, it would be an advantage - when occasionally needed - to be able to operate the propeller/main engine as much as possible to the left of line 6, but inside the torque/speed limit, line 4.

Such cases could be for:

- ships sailing in areas with very heavy weather
- ships operating in ice
- ships with two fixed pitch propellers/two main engines, where one propeller/one engine is declutched for one or the other reason.

The increase of the operating speed range between line 6 and line 4 of the standard load diagram, see Fig. 2.04.02, may be carried out as shown for the following engine Example with an extended load diagram for speed derated engine with increased light running.

Extended load diagram for speed derated engines with increased light running

The maximum speed limit (line 3) of the engines is 105% of the SMCR (Specified Maximum Continuous Rating) speed, as shown in Fig. 2.04.02.

However, for speed and, thereby, power derated engines it is possible to extend the maximum speed limit to 105% of the engine's nominal MCR speed, line 3', but only provided that the torsional vibration conditions permit this. Thus, the shafting, with regard to torsional vibrations, has to be approved by the classification society in question, based on the extended maximum speed limit.

When choosing an increased light running to be used for the design of the propeller, the load diagram area may be extended from line 3 to line 3', as shown in Fig. 2.04.03, and the propeller/main engine operating curve 6 may have a correspondingly increased heavy running margin before exceeding the torque/speed limit, line 4.

A corresponding slight reduction of the propeller efficiency may be the result, due to the higher propeller design speed used.
Examples of the use of the Load Diagram

In the following are some examples illustrating the flexibility of the layout and load diagrams.

• Example 1 shows how to place the load diagram for an engine without shaft generator coupled to a fixed pitch propeller.

• Example 2 shows the same layout for an engine with fixed pitch propeller (example 1), but with a shaft generator.

• Example 3 is a special case of example 2, where the specified MCR is placed near the top of the layout diagram. In this case the shaft generator is cut off, and the GenSets used when the engine runs at specified MCR. This makes it possible to choose a smaller engine with a lower power output, and with changed specified MCR.

• Example 4 shows diagrams for an engine coupled to a controllable pitch propeller, with or without a shaft generator, constant speed or combinator curve operation.

For a specific project, the layout diagram for actual project shown later in this chapter may be used for construction of the actual load diagram.
Example 1: Normal running conditions.
Engine coupled to fixed pitch propeller (FPP) and without shaft generator

</tbody>
</table>

The specified MCR (M) and its propeller curve 1 will normally be selected on the engine service curve 2.

Once point M has been selected in the layout diagram, the load diagram can be drawn, as shown in the figure, and hence the actual load limitation lines of the diesel engine may be found by using the inclinations from the construction lines and the %-figures stated.

Load diagram

Fig. 2.04.04: Normal running conditions. Engine coupled to a fixed pitch propeller (FPP) and without a shaft generator
Example 2: Normal running conditions. Engine coupled to fixed pitch propeller (FPP) and with shaft generator

**Layout diagram**

**Load diagram**

In example 2 a shaft generator (SG) is installed, and therefore the service power of the engine also has to incorporate the extra shaft power required for the shaft generator’s electrical power production.

In the figure, the engine service curve shown for heavy running incorporates this extra power.

The specified MCR M will then be chosen and the load diagram can be drawn as shown in the figure.

Fig. 2.04.06: Normal running conditions. Engine coupled to a fixed pitch propeller (FPP) and with a shaft generator
Example 3: Special running conditions.
Engine coupled to fixed pitch propeller (FPP) and with shaft generator

**Layout diagram**

- **M** Specified MCR of engine
- **S** Continuous service rating of engine
- **MP** Specified MCR for propulsion
- **SP** Continuous service rating of propulsion
- **SG** Shaft generator

Also for this special case in example 3, a shaft generator is installed but, compared to example 2, this case has a specified MCR for propulsion, MP, placed at the top of the layout diagram.

This involves that the intended specified MCR of the engine M’ will be placed outside the top of the layout diagram.

One solution could be to choose a larger diesel engine with an extra cylinder, but another and cheaper solution is to reduce the electrical power production of the shaft generator when running in the upper propulsion power range.

In choosing the latter solution, the required specified MCR power can be reduced from point M’ to point M as shown. Therefore, when running in the upper propulsion power range, a diesel generator has to take over all or part of the electrical power production.

However, such a situation will seldom occur, as ships are rather infrequently running in the upper propulsion power range.

Point M, having the highest possible power, is then found at the intersection of line L₁–L₃ with line 1 and the corresponding load diagram is drawn.

**Load diagram**

**Point M of the load diagram is found:**
- **Line 1** Propeller curve through point S
- **Point M** Intersection between line 1 and line L₁ – L₃

Fig. 2.04.07: Special running conditions. Engine coupled to a fixed pitch propeller (FPP) and with a shaft generator
Example 4: Engine coupled to controllable pitch propeller (CPP) with or without shaft generator

**Layout diagram - with shaft generator**

The hatched area shows the recommended speed range between 100% and 96.7% of the specified MCR speed for an engine with shaft generator running at constant speed.

The service point S can be located at any point within the hatched area.

The procedure shown in examples 2 and 3 for engines with FPP can also be applied here for engines with CPP running with a combinator curve.

**Load diagram**

Therefore, when the engine's specified MCR point (M) has been chosen including engine margin, sea margin and the power for a shaft generator, if installed, point M may be used in the load diagram, which can then be drawn.

The position of the combinator curve ensures the maximum load range within the permitted speed range for engine operation, and it still leaves a reasonable margin to the limit indicated by curves 4 and 5.

---

**Layout diagram - without shaft generator**

If a controllable pitch propeller (CPP) is applied, the combinator curve (of the propeller) will normally be selected for loaded ship including sea margin.

The combinator curve may for a given propeller speed have a given propeller pitch, and this may be heavy running in heavy weather like for a fixed pitch propeller.

Therefore it is recommended to use a light running combinator curve (the dotted curve which includes the sea power margin) as shown in the figure to obtain an increased operation margin of the diesel engine in heavy weather to the limit indicated by curves 4 and 5.
Diagram for actual project

This figure contains a layout diagram that can be used for constructing the load diagram for an actual project, using the %-figures stated and the inclinations of the lines.
Specific Fuel Oil Consumption, ME versus MC engines

As previously mentioned the main feature of the ME/ME-C engine is that the fuel injection and the exhaust valve timing are optimised automatically over the entire power range, and with a minimum speed down to around 15-20% of the L₁ speed, but around 20-25% for MC/MC-C.

Comparing the specific fuel oil consumption (SFOC) of the ME and the MC engines, it can be seen from the figure below that the great advantage of the ME engine is a lower SFOC at part loads.

It is also noted that the lowest SFOC for the ME/ME-C engine is at 70% of M, whereas it is at 80% of M for the MC/MC-C/ME-B engine.

For the ME engine only the turbocharger matching and the compression ratio (shims under the piston rod) remain as variables to be determined by the engine maker / MAN Diesel & Turbo.

The calculation of the expected specific fuel oil consumption (SFOC) valid for standard high load optimised engines can be carried out by means of the following figures for fixed pitch propeller and for controllable pitch propeller, constant speed.

Throughout the whole load area the SFOC of the engine depends on where the specified MCR point (M) is chosen.

*Fig. 2.06.01: Example of part load SFOC curves for ME and MC with fixed pitch propeller*
SFOC for High Efficiency Turbochargers

The S46MC-C8.2 is as standard fitted with high efficiency turbochargers, option: 4 59 107.

The high efficiency turbocharger is applied to the engine in the basic design with the view to obtaining the best possible Specific Fuel Oil Consumption (SFOC) values, see example in Fig. 2.07.01.

At part load running the lowest SFOC may be obtained at 80% of the specified MCR.

For more information visit: www.marine.man.eu → 'Two-Stroke' → 'Turbocharger Selection'.

Fig. 2.07.01: Example of part load SFOC curves for high efficiency turbochargers
SFOC reference conditions and guarantee

SFOC at reference conditions

The SFOC is given in g/kWh based on the reference ambient conditions stated in ISO 3046-1:2002(E) and ISO 15550:2002(E):

- 1,000 mbar ambient air pressure
- 25 °C ambient air temperature
- 25 °C scavenge air coolant temperature

and is related to a fuel oil with a lower calorific value of 42,700 kJ/kg (~10,200 kcal/kg).

Any discrepancies between g/kWh and g/BHP.h are due to the rounding of numbers for the latter.

For lower calorific values and for ambient conditions that are different from the ISO reference conditions, the SFOC will be adjusted according to the conversion factors in the table below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Condition change</th>
<th>With ( p_{\text{max}} ) adjusted</th>
<th>Without ( p_{\text{max}} ) adjusted</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scav. air coolant temperature</td>
<td>per 10 °C rise</td>
<td>+ 0.60%</td>
<td>+ 0.41%</td>
</tr>
<tr>
<td>Blower inlet temperature</td>
<td>per 10 °C rise</td>
<td>+ 0.20%</td>
<td>+ 0.71%</td>
</tr>
<tr>
<td>Blower inlet pressure</td>
<td>per 10 mbar rise</td>
<td>- 0.02%</td>
<td>- 0.05%</td>
</tr>
<tr>
<td>Fuel oil lower calorific value</td>
<td>rise 1% (42,700 kJ/kg)</td>
<td>-1.00%</td>
<td>- 1.00%</td>
</tr>
</tbody>
</table>

With for instance 1 °C increase of the scavenge air coolant temperature, a corresponding 1 °C increase of the scavenge air temperature will occur and involves an SFOC increase of 0.06% if \( p_{\text{max}} \) is adjusted to the same value.

SFOC guarantee

The Energy Efficiency Design Index (EEDI) has increased the focus on part-load SFOC. We therefore offer the option of selecting the SFOC guarantee at a load point in the range between 50% and 100%, EoD: 4 02 002.

All engine design criteria, e.g. heat load, bearing load and mechanical stresses on the construction are defined at 100% load independent of the guarantee point selected. This means that turbocharger matching, engine adjustment and engine load calibration must also be performed at 100% independent of guarantee point. At 100% load, the SFOC tolerance is 5%.

When choosing an SFOC guarantee below 100%, the tolerances, which were previously compensated for by the matching, adjustment and calibration at 100%, will affect engine running at the lower SFOC guarantee load point. This includes tolerances on measurement equipment, engine process control and turbocharger performance.

Consequently, SFOC guarantee tolerances are:

- 100% – 85%: 5% tolerance
- 84% – 65%: 6% tolerance
- 64% – 50%: 7% tolerance

Please note that the SFOC guarantee can only be given in one (1) load point.

Recommended cooling water temperature during normal operation

In general, it is recommended to operate the main engine with the lowest possible cooling water temperature to the air coolers, as this will reduce the fuel consumption of the engine, i.e. the engine performance will be improved.

However, shipyards often specify a constant (maximum) central cooling water temperature of 36 °C, not only for tropical ambient temperature conditions, but also for lower ambient temperature conditions. The purpose is probably to reduce the electric power consumption of the cooling water pumps and/or to reduce water condensation in the air coolers.

Thus, when operating with 36 °C cooling water instead of for example 10 °C (to the air coolers), the specific fuel oil consumption will increase by approx. 2 g/kWh.
Examples of Graphic Calculation of SFOC

The examples shown in Fig. 2.09 and 2.10 are valid for a standard high-load optimised engine.

The following Diagrams a, b and c, valid for fixed pitch propeller (b) and constant speed (c), respectively, show the reduction of SFOC in g/kWh, relative to the SFOC for the nominal MCR L₁ rating.

The solid lines are valid at 100%, 80% and 50% of SMCR point M.

Point M is drawn into the above-mentioned Diagrams b or c. A straight line along the constant mep curves (parallel to L₁⁻L₃) is drawn through point M. The intersections of this line and the curves indicate the reduction in specific fuel oil consumption at 100, 80 and 50% of the SMCR point M, related to the SFOC stated for the nominal MCR L₁ rating.

An example of the calculated SFOC curves are shown in Diagram a, and is valid for an engine with fixed pitch propeller, see Fig. 2.10.01.

Fuel Consumption at an Arbitrary Load

Once the specified MCR (M) of the engine has been chosen, the specific fuel oil consumption at an arbitrary point S₁, S₂ or S₃ can be estimated based on the SFOC at point ‘1’ and ‘2’.

These SFOC values can be calculated by using the graphs for the relevant engine type for the propeller curve I and for the constant speed curve II, giving the SFOC at points 1 and 2, respectively.

Next the SFOC for point S₁ can be calculated as an interpolation between the SFOC in points ‘1’ and ‘2’, and for point S₃ as an extrapolation.

The SFOC curve through points S₂, on the left of point 1, is symmetrical about point 1, i.e. at speeds lower than that of point 1, the SFOC will also increase.

The above-mentioned method provides only an approximate value. A more precise indication of the expected SFOC at any load can be calculated by using our computer program. This is a service which is available to our customers on request.

Turbocharger Selection & Exhaust Gas By-pass
### Turbocharger Selection

Updated turbocharger data based on the latest information from the turbocharger makers are available from the Turbocharger Selection program on www.marine.man.eu → 'Two-Stroke' → 'Turbocharger Selection'.

The data specified in the printed edition are valid at the time of publishing.

The MC/ME engines are designed for the application of either MAN Diesel, ABB or Mitsubishi (MHI) turbochargers.

The turbocharger choice is made with a view to obtaining the lowest possible Specific Fuel Oil Consumption (SFOC) values at the nominal MCR by applying conventional turbochargers.

The engines are, as standard, equipped with as few turbochargers as possible, see the table in Fig. 3.01.01.

One more turbocharger can be applied, than the number stated in the tables, if this is desirable due to space requirements, or for other reasons. Additional costs are to be expected.

However, we recommend the 'Turbocharger selection' programme on the Internet, which can be used to identify a list of applicable turbochargers for a specific engine layout.

For information about turbocharger arrangement and cleaning systems, see Section 15.01.

Emission Control

IMO Tier II NO\textsubscript{x} emission limits

All MC and MC-C engines are, as standard, fulfilling the IMO Tier II NO\textsubscript{x} emission requirements, a speed dependent NO\textsubscript{x} limit measured according to ISO 8178 Test Cycles E2/E3 for Heavy Duty Diesel Engines.

0-30% NO\textsubscript{x} reduction

The MC and MC-C engines are as standard delivered to comply with IMO NO\textsubscript{x} emission limitations, EoD: 4 06 200 Economy mode. Engine test cycles E2 and E3 has to be ordered as an option: 4 06 201 and 202, and various conditions can be specified, options: 4 06 206, 207 and 208. Compliance with other emission limits can be specified as an option: 4 06 225.

Regardless of the emission limit specified, the engines are matched for best economy in service.

NO\textsubscript{x} reduction methods for IMO Tier III

As adopted by IMO for future enforcement, the engine must fulfil the more restrictive IMO Tier III NO\textsubscript{x} requirements when sailing in a NO\textsubscript{x} Emission Control Area (NO\textsubscript{x} ECA).

The Tier III NO\textsubscript{x} requirements can be met by Exhaust Gas Recirculation (EGR), a method which directly affects the combustion process by lowering the generation of NO\textsubscript{x}.

Alternatively, the required NO\textsubscript{x} level could be met by installing Selective Catalytic Reaction (SCR), an after treatment system that reduces the emission of NO\textsubscript{x} already generated in the combustion process.

Details of MAN Diesel & Turbo’s NO\textsubscript{x} reduction methods for IMO Tier III can be found in our publication: 

Emission Project Guide

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Project Guides' → 'Other Guides'.
Electricity Production
Electricity Production

Introduction

Next to power for propulsion, electricity production is the largest fuel consumer on board. The electricity is produced by using one or more of the following types of machinery, either running alone or in parallel:

- Auxiliary diesel generating sets
- Main engine driven generators
- Steam driven turbogenerators
- Emergency diesel generating sets.

The machinery installed should be selected on the basis of an economic evaluation of first cost, operating costs, and the demand for man-hours for maintenance.

In the following, technical information is given regarding main engine driven generators (PTO) and the auxiliary diesel generating sets produced by MAN Diesel & Turbo.

Power Take Off

With a generator coupled to a Power Take Off (PTO) from the main engine, electrical power can be produced based on the main engine’s low SFOC and the use of heavy fuel oil. Several standardised PTO systems are available, see Fig. 4.01.01 and the designations in Fig. 4.01.02:

- PTO/GCR  
  (Power Take Off/Gear Constant Ratio): Generator coupled to a constant ratio step-up gear, used only for engines running at constant speed.

Within each PTO system, several designs are available, depending on the positioning of the gear:

- BW II: A free-standing gear mounted on the tank top and connected to the fore end of the diesel engine, with a vertical or horizontal generator.
- BW IV: A free-standing step-up gear connected to the intermediate shaft, with a horizontal generator.

*Fig. 4.01.02: Example of designation of PTO*
PTO/RCF

Free standing generator, BW II/RCF
(Fig. 4.01.01, alternative 2)

The PTO/RCF generator systems have been developed in close cooperation with the German gear manufacturer RENK. A complete package solution is offered, comprising a flexible coupling, a step-up gear, an epicyclic, variable-ratio gear with built-in clutch, hydraulic pump and motor, and a standard generator.

For marine engines with controllable pitch propellers running at constant engine speed, the hydraulic system can be dispensed with, i.e. a PTO/GCR design is normally used, see Fig. 4.01.01, alternative 5 or 6.

Fig. 4.01.03 shows the principles of the PTO/RCF arrangement.

The epicyclic gear of the BW II/RCF unit has a hydrostatic superposition drive. The hydrostatic input drives the annulus of the epicyclic gear in either direction of rotation, hence continuously varying the gearing ratio to keep the generator speed constant throughout an engine speed variation of 30%. In the standard layout, this is between 100% and 70% of the engine speed at specified MCR, but it can be placed in a lower range if required.

The input power to the gear is divided into two paths – one mechanical and the other hydrostatic – and the epicyclic differential combines the power of the two paths and transmits the combined power to the output shaft, connected to the generator. The gear is equipped with a hydrostatic motor driven by a pump, and controlled by an electronic control unit.

**Fig. 4.01.03: PTO with RENK constant frequency gear: BW II/RCF, option: 4 85 203**
This keeps the generator speed constant during single running as well as when running in parallel with other generators.

The multi-disc clutch, integrated into the gear input shaft, permits the engaging and disengaging of the epicyclic gear, and thus the generator, from the main engine during operation.

An electronic control system with a RENK controller ensures that the control signals to the main electrical switchboard are identical to those for the normal auxiliary generator sets. This applies to ships with automatic synchronising and load sharing, as well as to ships with manual switchboard operation.

Internal control circuits and interlocking functions between the epicyclic gear and the electronic control box provide automatic control of the functions necessary for the satisfactory operation and protection of the BW II/RCF unit. If any monitored value exceeds the normal operation limits, a warning or an alarm is given depending upon the origin, severity and the extent of deviation from the permissible values. The cause of a warning or an alarm is shown on a digital display.

The delivery is a complete separate unit.

In the case that a larger generator is required, please contact MAN Diesel & Turbo.

Yard deliveries are:

1. Cooling water pipes to the built-on lubricating oil cooling system, including the valves
2. Electrical power supply to the lubricating oil stand-by pump built on to the RCF unit
3. Wiring between the generator and the operator control panel in the switch-board.
4. An external permanent lubricating oil filling-up connection can be established in connection with the RCF unit.

The necessary preparations to be made on the engine are specified in Fig. 4.03.01.
Space requirements have to be investigated on plants with the turbocharger on the exhaust side, Space requirements for a larger generator has to be investigated case by case.

Dimension H: This is only valid for A. van Kaick generator type DSG, enclosure IP23, frequency = 60 Hz, speed = 1,800 r/min

**Fig. 4.02.01: Space requirement for side mounted generator PTO/RCF type BWlll S46-C/RCF**
Engine preparations for PTO BW II

1. Flange on crankshaft
2. Studs and nuts, dowel pipe and screws
3. Intermediate shaft between the crankshaft and flexible coupling for PTO
4. Oil sealing for intermediate shaft
5. End cover in 2/2 with scraper ring housing
6. Plug box for electronic measuring instrument for check of condition of axial vibration damper

Fig. 4.03.01: Engine preparations for PTO
PTO type: BW II/GCR

Power Take Off/Gear Constant Ratio

The PTO system type BW II/GCR illustrated in Fig. 4.01.01 alternative 5 can generate electrical power on board ships equipped with a controllable pitch propeller, running at constant speed.

The PTO unit is mounted on the tank top at the fore end of the engine see Fig. 4.04.01. The PTO generator is activated at sea, taking over the electrical power production on board when the main engine speed has stabilised at a level corresponding to the generator frequency required on board.

The installation length in front of the engine, and thus the engine room length requirement, naturally exceeds the length of the engine aft end mounted shaft generator arrangements. However, there is some scope for limiting the space requirement, depending on the configuration chosen.

PTO type: BW IV/GCR

Power Take Off/Gear Constant Ratio

The shaft generator system, type PTO BW IV/GCR, installed in the shaft line (Fig. 4.01.01 alternative 6) can generate power on board ships equipped with a controllable pitch propeller running at constant speed.

The PTO system can be delivered as a tunnel gear with hollow flexible coupling or, alternatively, as a generator step-up gear with thrust bearing and flexible coupling integrated in the shaft line.

The main engine needs no special preparation for mounting these types of PTO systems as they are connected to the intermediate shaft.

The PTO system installed in the shaft line can also be installed on ships equipped with a fixed pitch propeller or controllable pitch propeller running in

---

**Fig. 4.04.01: Generic outline of Power Take Off (PTO) BW II/GCR**
combinator mode. This will, however, require an additional RENK Constant Frequency gear (Fig. 4.01.01 alternative 2) or additional electrical equipment for maintaining the constant frequency of the generated electric power.

**Tunnel gear with hollow flexible coupling**

This PTO system is normally installed on ships with a minor electrical power take off load compared to the propulsion power, up to approximately 25% of the engine power.

The hollow flexible coupling is only to be dimensioned for the maximum electrical load of the power take off system and this gives an economic advantage for minor power take off loads compared to the system with an ordinary flexible coupling integrated in the shaft line.

The hollow flexible coupling consists of flexible segments and connecting pieces, which allow replacement of the coupling segments without dismounting the shaft line, see Fig. 4.04.02.

**Generator step-up gear and flexible coupling integrated in the shaft line**

For higher power take off loads, a generator step-up gear and flexible coupling integrated in the shaft line may be chosen due to first costs of gear and coupling.

The flexible coupling integrated in the shaft line will transfer the total engine load for both propulsion and electrical power and must be dimensioned accordingly.

The flexible coupling cannot transfer the thrust from the propeller and it is, therefore, necessary to make the gear-box with an integrated thrust bearing.

This type of PTO system is typically installed on ships with large electrical power consumption, e.g. shuttle tankers.

*Fig. 4.04.02: Generic outline of BW IV/GCR, tunnel gear*
**Auxiliary Propulsion System/Take Home System**

From time to time an Auxiliary Propulsion System/Take Home System capable of driving the CP propeller by using the shaft generator as an electric motor is requested.

MAN Diesel & Turbo can offer a solution where the CP propeller is driven by the alternator via a two-speed tunnel gear box. The electric power is produced by a number of GenSets. The main engine is disengaged by a clutch (RENK PSC) made as an integral part of the shafting. The clutch is installed between the tunnel gear box and the main engine, and conical bolts are used to connect and disconnect the main engine and the shafting. See Figure 4.04.03.

A thrust bearing, which transfers the auxiliary propulsion propeller thrust to the engine thrust bearing when the clutch is disengaged, is built into the RENK PSC clutch. When the clutch is engaged, the thrust is transferred statically to the engine thrust bearing through the thrust bearing built into the clutch.

To obtain high propeller efficiency in the auxiliary propulsion mode, and thus also to minimise the auxiliary power required, a two-speed tunnel gear, which provides lower propeller speed in the auxiliary propulsion mode, is used.

The two-speed tunnel gear box is made with a friction clutch which allows the propeller to be clutched in at full alternator/motor speed where the full torque is available. The alternator/motor is started in the de-clutched condition with a start transformer.

The system can quickly establish auxiliary propulsion from the engine control room and/or bridge, even with unmanned engine room.

Re-establishment of normal operation requires attendance in the engine room and can be done within a few minutes.

---

---

**Notes:**

1) LT cooling water flow first through LT stage charge air cooler, then through lube oil cooler, water temperature outlet engine regulated by mechanical thermostat.

2) HT cooling water flow first through HT stage charge air cooler, then through water jacket and cylinder head, water temperature outlet engine regulated by mechanical thermostat.

3) Tolerance: +10% for rating coolers, -15% for heat recovery.

4) Basic values for layout of the coolers.

5) Under above mentioned reference conditions.

6) Tolerance: quantity +/- 5%, temperature +/- 20°C.

7) Under below mentioned temperature at turbine outlet and pressure according above mentioned reference conditions.

8) Tolerance of the pumps delivery capacities must be considered by the manufactures.

Fig. 4.08.02b: List of capacities for L23/30H, 900 rpm, IMO Tier II
Installation Aspects
Space Requirements and Overhaul Heights

The latest version of most of the drawings of this section is available for download at www.marine.man.eu → 'Two-Stroke' → 'Installation Drawings'. First choose engine series, then engine type and select from the list of drawings available for download.

Space Requirements for the Engine

The space requirements stated in Section 5.02 are valid for engines rated at nominal MCR (L₁).

The additional space needed for engines equipped with PTO is stated in Chapter 4.

If, during the project stage, the outer dimensions of the turbocharger seem to cause problems, it is possible, for the same number of cylinders, to use turbochargers with smaller dimensions by increasing the indicated number of turbochargers by one, see Chapter 3.

Overhaul of Engine

The distances stated from the centre of the crankshaft to the crane hook are for the normal lifting procedure and the reduced height lifting procedure (involving tilting of main components). The lifting capacity of a normal engine room crane can be found in Fig. 5.04.01.

The area covered by the engine room crane shall be wide enough to reach any heavy spare part required in the engine room.

A lower overhaul height is, however, available by using the MAN B&W Double-Jib crane, built by Danish Crane Building A/S, shown in Figs. 5.04.02 and 5.04.03.

Please note that the distance 'E' in Fig. 5.02.01, given for a double-jib crane is from the centre of the crankshaft to the lower edge of the deck beam.

A special crane beam for dismantling the turbocharger must be fitted. The lifting capacity of the crane beam for dismantling the turbocharger is stated in Section 5.03.

The overhaul tools for the engine are designed to be used with a crane hook according to DIN 15400, June 1990, material class M and load capacity 1Am and dimensions of the single hook type according to DIN 15401, part 1.

The total length of the engine at the crankshaft level may vary depending on the equipment to be fitted on the fore end of the engine, such as adjustable counterweights, tuning wheel, moment compensators or PTO.
Crane beam for overhaul of turbocharger

For the overhaul of a turbocharger, a crane beam with trolleys is required at each end of the turbocharger.

Two trolleys are to be available at the compressor end and one trolley is needed at the gas inlet end.

Crane beam no. 1 is for dismantling of turbocharger components.
Crane beam no. 2 is for transporting turbocharger components.
See Figs. 5.03.01a and 5.03.02.

The crane beams can be omitted if the main engine room crane also covers the turbocharger area.

The crane beams are used and dimensioned for lifting the following components:
- Exhaust gas inlet casing
- Turbocharger inlet silencer
- Compressor casing
- Turbine rotor with bearings

The crane beams are to be placed in relation to the turbocharger(s) so that the components around the gas outlet casing can be removed in connection with overhaul of the turbocharger(s).

The crane beam can be bolted to brackets that are fastened to the ship structure or to columns that are located on the top platform of the engine.

The lifting capacity of the crane beam for the heaviest component ‘W’, is indicated in Fig. 5.03.01b for the various turbocharger makes. The crane beam shall be dimensioned for lifting the weight ‘W’ with a deflection of some 5 mm only.

HB indicates the position of the crane hook in the vertical plane related to the centre of the turbocharger. HB and b also specifies the minimum space for dismantling.

For engines with the turbocharger(s) located on the exhaust side, EoD No. 4 59 122, the letter ‘a’ indicates the distance between vertical centrelines of the engine and the turbocharger.

**Fig. 5.03.01a: Required height and distance**

**Fig. 5.03.01b: Required height and distance and weight**
Crane beam for turbochargers

Fig. 5.03.02: Crane beam for turbocharger
Crane beam for overhaul of air cooler
Overhaul/exchange of scaveng e air cooler.

Valid for air cooler design for the following engines with more than one turbochargers mounted on the exhaust side.

1. Dismantle all the pipes in the area around the air cooler.

2. Dismantle all the pipes around the inlet cover for the cooler.

3. Take out the cooler insert by using the above placed crane beam mounted on the engine.

4. Turn the cooler insert to an upright position.

5. Dismantle the platforms below the air cooler.

6. Lower down the cooler insert between the gallery brackets and down to the engine room floor. Make sure that the cooler insert is supported, e.g. on a wooden support.

7. Move the air cooler insert to an area covered by the engine room crane using the lifting beam mounted below the lower gallery of the engine.

8. By using the engine room crane the air cooler insert can be lifted out of the engine room.

---

Fig.: 5.03.03: Crane beam for overhaul of air cooler, turbochargers located on exhaust side of the engine
Crane beam for overhaul of air cooler

Overhaul/exchange of scavenge air cooler.

The text and figures are for guidance only.

Valid for all engines with aft mounted Turbocharger.

1. Dismantle all the pipes in the area around the air cooler.
2. Dismantle all the pipes around the inlet cover for the cooler.
3. Take out the cooler insert by using the above placed crane beam mounted on the engine.
4. Turn the cooler insert to an upright position.
5. By using the engine room crane the air cooler insert can be lifted out of the engine room.

Fig.: 5.03.04: Crane beam for overhaul of air cooler, turbocharger located on aft end of the engine
Engine room crane

1) The lifting tools for the engine are designed to fit together with a standard crane hook with a lifting capacity in accordance with the figure stated in the table. If a larger crane hook is used, it may not fit directly to the overhaul tools, and the use of an intermediate shackle or similar between the lifting tool and the crane hook will affect the requirements for the minimum lifting height in the engine room (dimension B).

2) The hatched area shows the height where an MAN B&W Double-Jib Crane has to be used.

<tr>
<td>1,450</td>
<td>1,575</td>
<td>800</td>
<td>2.0</td>
<td>2x1.0</td>
</tr>
</tbody>
</table>

The crane hook travelling area must cover at least the full length of the engine and a width in accordance with dimension A given on the drawing, see cross-hatched area.

It is furthermore recommended that the engine room crane can be used for transport of heavy spare parts from the engine room hatch to the spare part stores and to the engine. See example on this drawing.

The crane hook should at least be able to reach down to a level corresponding to the centre line of the crankshaft.

For overhaul of the turbocharger(s), trolley mounted chain hoists must be installed on a separate crane beam or, alternatively, in combination with the engine room crane structure, see ‘Crane beam for overhaul of turbochargers’ with information about the required lifting capacity for overhaul of turbocharger(s).
Overhaul with MAN B&W Double-Jib Crane

The MAN B&W Double-Jib crane is available from:

Danish Crane Building A/S
P.O. Box 54
Østerlandsvej 2
DK-9240 Nibe, Denmark
Telephone: + 45 98 35 31 33
Telefax: + 45 98 35 30 33
E-mail: dcb@dcb.dk

Fig. 5.04.02: Overhaul with Double-Jib crane
MAN B&W Double-Jib Crane

This crane is adapted to the special tool for low overhaul.

Dimensions are available on request.

Engine Outline, Galleries and Pipe Connections

Engine outline

The total length of the engine at the crankshaft level may vary depending on the equipment to be fitted on the fore end of the engine, such as adjustable counterweights, tuning wheel, moment compensators or PTO, which are shown as alternatives in Section 5.06.

Engine masses and centre of gravity

The partial and total engine masses appear from Section 19.04, ‘Dispatch Pattern’, to which the masses of water and oil in the engine, Section 5.08, are to be added. The centre of gravity is shown in Section 5.07, in both cases including the water and oil in the engine, but without moment compensators or PTO.

Gallery outline

Section 5.06 show the gallery outline for engines rated at nominal MCR (L1).

Engine pipe connections

The positions of the external pipe connections on the engine are stated in Section 5.09, and the corresponding lists of counterflanges for pipes and turbocharger in Section 5.10.

The flange connection on the turbocharger gas outlet is rectangular, but a transition piece to a circular form can be supplied as an option: 4 60 601.
Engine and Gallery Outline

Fig. 5.06.01a: Engine outline, 6S46MC-C8 with turbocharger on aft end

Please note that the latest version of the dimensioned drawing is available for download at www.marine.man.eu → 'Two-Stroke' → 'Installation Drawings'. First choose engine series, then engine type and select 'Outline drawing' for the actual number of cylinders and type of turbocharger installation in the list of drawings available for download.

For platform dimensions, see 'Gallery Outline'.

Engine Seating and Holding Down Bolts

The latest version of most of the drawings of this section is available for download at www.marine.man.eu → ‘Two-Stroke’ → ‘Installation Drawings’. First choose engine series, then engine type and select ‘Engine seating’ in the general section of the list of drawings available for download.

Engine seating and arrangement of holding down bolts

The dimensions of the seating stated in Figs. 5.12.01 and 5.12.02 are for guidance only.

The engine is designed for mounting on epoxy chocks, EoD: 4 82 102, in which case the underside of the bedplate’s lower flanges has no taper.

The epoxy types approved by MAN Diesel & Turbo are:

- ‘Chockfast Orange PR 610 TCF’ from ITW Philadelphia Resins Corporation, USA
- ‘Durasin’ from Daemmstoff Industrie Korea Ltd
- ‘Epocast 36’ from H.A. Springer - Kiel, Germany
- ‘EPY’ from Marine Service Jaroszewicz S.C., Poland
- ‘Loctite Fixmaster Marine Chocking’, Henkel
Epoxy Chocks Arrangement

For details of chocks and bolts see special drawings.

For securing of supporting chocks see special drawing.

This drawing may, subject to the written consent of the actual engine builder concerned, be used as a basis for marking-off and drilling the holes for holding down bolts in the top plates, provided that:

1) The engine builder drills the holes for holding down bolts in the bedplate while observing the toleranced locations indicated on MAN B&W drawings for machining the bedplate.

2) The shipyard drills the holes for holding down bolts in the top plates while observing the toleranced locations given on the present drawing.

3) The holding down bolts are made in accordance with MAN B&W drawings of these bolts.

**Engine Top Bracing**

The so-called guide force moments are caused by the transverse reaction forces acting on the crossheads due to the connecting rod and crankshaft mechanism. When the piston of a cylinder is not exactly in its top or bottom position the gas force from the combustion, transferred through the connecting rod, will have a component acting on the crosshead and the crankshaft perpendicularly to the axis of the cylinder. Its resultant is acting on the guide shoe and together they form a guide force moment.

The moments may excite engine vibrations moving the engine top athwartships and causing a rocking (excited by H-moment) or twisting (excited by X-moment) movement of the engine. For engines with less than seven cylinders, this guide force moment tends to rock the engine in the transverse direction, and for engines with seven cylinders or more, it tends to twist the engine.

The guide force moments are harmless to the engine except when resonance vibrations occur in the engine/double bottom system. They may, however, cause annoying vibrations in the superstructure and/or engine room, if proper countermeasures are not taken.

As a detailed calculation of this system is normally not available, MAN Diesel & Turbo recommends that top bracing is installed between the engine's upper platform brackets and the casing side.

However, the top bracing is not needed in all cases. In some cases the vibration level is lower if the top bracing is not installed. This has normally to be checked by measurements, i.e. with and without top bracing.

If a vibration measurement in the first vessel of a series shows that the vibration level is acceptable without the top bracing, we have no objection to the top bracing being removed and the rest of the series produced without top bracing. It is our experience that especially the 7-cylinder engine will often have a lower vibration level without top bracing.

**Without top bracing**, the natural frequency of the vibrating system comprising engine, ship's bottom, and ship's side is often so low that resonance with the excitation source (the guide force moment) can occur close to the normal speed range, resulting in the risk of vibration.

**With top bracing**, such a resonance will occur above the normal speed range, as the natural frequencies of the double bottom/main engine system will increase. The impact of vibration is thus lowered.

The top bracing is normally installed on the exhaust side of the engine, but can alternatively be installed on the manoeuvring side. A combination of exhaust side and manoeuvring side installation is also possible.

The top bracing system is installed either as a mechanical top bracing or a hydraulic top bracing. Both systems are described below.

**Mechanical top bracing**

The mechanical top bracing comprises stiff connections between the engine and the hull.

The top bracing stiffener consists of a double bar tightened with friction shims at each end of the mounting positions. The friction shims allow the top bracing stiffener to move in case of displacements caused by thermal expansion of the engine or different loading conditions of the vessel. Furthermore, the tightening is made with a well-defined force on the friction shims, using disc springs, to prevent overloading of the system in case of an excessive vibration level.
The mechanical top bracing is to be made by the shipyard in accordance with MAN Diesel & Turbo instructions.

Fig. 5.13.01: Mechanical top bracing stiffener. Option: 4 83 112

**Hydraulic top bracing**

The hydraulic top bracing is an alternative to the mechanical top bracing used mainly on engines with a cylinder bore of 50 or more. The installation normally features two, four or six independently working top bracing units.

The top bracing unit consists of a single-acting hydraulic cylinder with a hydraulic control unit and an accumulator mounted directly on the cylinder unit.

The top bracing is controlled by an automatic switch in a control panel, which activates the top bracing when the engine is running. It is possible to programme the switch to choose a certain rpm range, at which the top bracing is active. For service purposes, manual control from the control panel is also possible.

When active, the hydraulic cylinder provides a pressure on the engine in proportion to the vibration level. When the distance between the hull and engine increases, oil flows into the cylinder under pressure from the accumulator. When the distance decreases, a non-return valve prevents the oil from flowing back to the accumulator, and the pressure rises. If the pressure reaches a preset maximum value, a relief valve allows the oil to flow back to the accumulator, hereby maintaining the force on the engine below the specified value.

By a different pre-setting of the relief valve, the top bracing is delivered in a low-pressure version (26 bar) or a high-pressure version (40 bar).

The top bracing unit is designed to allow displacements between the hull and engine caused by thermal expansion of the engine or different loading conditions of the vessel.

Horizontal vibrations on top of engine are caused by the guide force moments. For 4-7 cylinder en-gines the H-moment is the major excitation source and for larger cylinder numbers an X-moment is the major excitation source.

For engines with vibrations excited by an X-moment, bracing at the centre of the engine are of only minor importance.

Top bracing should only be installed on one side, either the exhaust side or the manoeuvring side. If top bracing has to be installed on manoeuvring side, please contact MAN Diesel & Turbo.

If the minimum built-in length can not be fulfilled, please contact MAN Diesel & Turbo or our local representative.

The complete arrangement to be delivered by the shipyard.

Fig. 5.14: Mechanical top bracing arrangement
Components for Engine Control System

This section is not applicable
Shaftline Earthing Device

Scope and field of application

A difference in the electrical potential between the hull and the propeller shaft will be generated due to the difference in materials and to the propeller being immersed in sea water.

In some cases, the difference in the electrical potential has caused spark erosion on the thrust, main bearings and journals of the crankshaft of the engine.

In order to reduce the electrical potential between the crankshaft and the hull and thus prevent spark erosion, a highly efficient shaftline earthing device must be installed.

The shaftline earthing device should be able to keep the electrical potential difference below 50 mV DC. A shaft-to-hull monitoring equipment with a mV-meter and with an output signal to the alarm system must be installed so that the potential and thus the correct function of the shaftline earthing device can be monitored.

Note that only one shaftline earthing device is needed in the propeller shaft system.

Design description

The shaftline earthing device consists of two silver slip rings, two arrangements for holding brushes including connecting cables and monitoring equipment with a mV-meter and an output signal for alarm.

The slip rings should be made of solid silver or back-up rings of cobber with a silver layer all over. The expected life span of the silver layer on the slip rings should be minimum 5 years.

The brushes should be made of minimum 80% silver and 20% graphite to ensure a sufficient electrical conducting capability.

Resistivity of the silver should be less than 0.1μ Ohm x m. The total resistance from the shaft to the hull must not exceed 0.001 Ohm.
Shaftline earthing device installations

The shaftline earthing device slip rings must be mounted on the foremost intermediate shaft as close to the engine as possible, see Fig. 5.17.02.
When a generator is fitted in the propeller shaft system, where the rotor of the generator is part of the intermediate shaft, the shaftline earthing device must be mounted between the generator and the engine, see Fig. 5.17.03.

Fig. 5.17.03: Installation of shaftline earthing device in an engine plant with shaft-mounted generator
MAN Alpha Controllable Pitch Propeller and Alphatronic Propulsion Control

MAN Diesel & Turbo’s MAN Alpha Controllable Pitch propeller

On MAN Diesel & Turbo’s MAN Alpha VBS type Controllable Pitch (CP) propeller, the hydraulic servo motor setting the pitch is built into the propeller hub. A range of different hub sizes is available to select an optimum hub for any given combination of power, revolutions and ice class.

Standard blade/hub materials are Ni-Al-bronze. Stainless steel is available as an option. The propellers are based on ‘no ice class’ but are available up to the highest ice classes.

VBS type CP propeller designation and range

The VBS type CP propellers are designated according to the diameter of their hubs, i.e. ‘VBS2150’ indicates a propeller hub diameter of 2,150 mm.

The standard VBS type CP propeller programme, its diameters and the engine power range covered is shown in Fig. 5.18.01.

The servo oil system controlling the setting of the propeller blade pitch is shown in Fig. 5.18.05.

![Graph showing propeller diameter vs engine power](image)

**Hub sizes:**
- Small: VBS600 - 940
- Medium: VBS1020 - 1640
- Large: VBS1730 - 2150

**Fig. 5.18.01:** MAN Alpha type VBS Mk 5 Controllable Pitch (CP) propeller range. As standard the VBS Mk 5 versions are 4-bladed; 5-bladed versions are available on request.

Propeller clearance

To reduce pressure impulses and vibrations emitted from the propeller to the hull, MAN Diesel & Turbo recommends a minimum tip clearance as shown in Fig. 5.18.04.

For ships with slender aft body and favourable inflow conditions the lower values can be used, whereas full afterbody and large variations in wake field cause the upper values to be used.

In twin-screw ships the blade tip may protrude below the base line.

</table>
Servo oil system for VBS type CP propeller

The design principle of the servo oil system for MAN Diesel & Turbo’s MAN Alpha VBS type CP propeller is shown in Fig. 5.18.05.

The VBS system consists of a servo oil tank unit, the Hydraulic Power Unit, and a coupling flange with electrical pitch feedback box and oil distributor ring.

The electrical pitch feedback box continuously measures the position of the pitch feedback ring and compares this signal with the pitch order signal.

If deviation occurs, a proportional valve is actuated. Hereby high pressure oil is fed to one or the other side of the servo piston, via the oil distributor ring, until the desired propeller pitch has been reached.

The pitch setting is normally remote controlled, but local emergency control is possible.

Fig. 5.18.05: Servo oil system for MAN Alpha VBS type CP propeller
Hydraulic Power Unit for MAN Alpha CP propeller

The servo oil tank unit, the Hydraulic Power Unit for MAN Diesel & Turbo’s MAN Alpha CP propeller shown in Fig. 5.18.06, consists of an oil tank with all other components top mounted to facilitate installation at yard.

Two electrically driven pumps draw oil from the oil tank through a suction filter and deliver high pressure oil to the proportional valve.

One of two pumps are in service during normal operation, while the second will start up at powerful manoeuvring.

A servo oil pressure adjusting valve ensures minimum servo oil pressure at any time hereby minimizing the electrical power consumption.

Maximum system pressure is set on the safety valve.

The return oil is led back to the tank via a thermostatic valve, cooler and paper filter.

The servo oil unit is equipped with alarms according to the Classification Society’s requirements as well as necessary pressure and temperature indicators.

If the servo oil unit cannot be located with maximum oil level below the oil distribution ring, the system must incorporate an extra, small drain tank complete with pump, located at a suitable level, below the oil distributor ring drain lines.

Fig. 5.18.06: Hydraulic Power Unit for MAN Alpha CP propeller, the servo oil tank unit
MAN Diesel & Turbo’s MAN Alphatronic 2000 Propulsion Control System (PCS) is designed for control of propulsion plants based on diesel engines with CP propellers. The plant could for instance include tunnel gear with PTO/PTI, PTO gear, multiple engines on one gearbox as well as multiple propeller plants.

As shown in Fig. 5.18.07, the propulsion control system comprises a computer controlled system with interconnections between control stations via a redundant bus and a hard wired back-up control system for direct pitch control at constant shaft speed.

The computer controlled system contains functions for:

- Machinery control of engine start/stop, engine load limits and possible gear clutches.
- Thrust control with optimization of propeller pitch and shaft speed. Selection of combinator, constant speed or separate thrust mode is possible. The rates of changes are controlled to ensure smooth manoeuvres and avoidance of propeller cavitation.
- A Load control function protects the engine against overload. The load control function contains a scavenge air smoke limiter, a load programme for avoidance of high thermal stresses in the engine, an automatic load reduction and an engineer controlled limitation of maximum load.
- Functions for transfer of responsibility between the local control stand, engine control room and control locations on the bridge are incorporated in the system.

Fig. 5.18.07: MAN Alphatronic 2000 Propulsion Control System
Propulsion control station on the main bridge

For remote control, a minimum of one control station located on the bridge is required.

This control station will incorporate three modules, as shown in Fig. 5.18.08:

- **Propulsion control panel** with push buttons and indicators for machinery control and a display with information of condition of operation and status of system parameters.

- **Propeller monitoring panel** with back-up instruments for propeller pitch and shaft speed.

- **Thrust control panel** with control lever for thrust control, an emergency stop button and push buttons for transfer of control between control stations on the bridge.

Fig. 5.18.08: Main bridge station standard layout
Renk PSC Clutch for auxilliary propulsion systems

The Renk PSC Clutch is a shaftline de-clutching device for auxilliary propulsion systems which meets the class notations for redundant propulsion.

The Renk PSC clutch facilitates reliable and simple ‘take home’ and ‘take away’ functions in two-stroke engine plants. It is described in Section 4.04.

Further information about MAN Alpha CP propeller

For further information about MAN Diesel & Turbo’s MAN Alpha Controllable Pitch (CP) propeller and the Alphatronic 2000 Remote Control System, please refer to our publications:

*CP Propeller – Product Information*

*Alphatronic 2000 PCS Propulsion Control System*

The publications are available at [www.marine.man.eu → 'Propeller & Aft Ship'].

List of Capacities: Pumps, Coolers & Exhaust Gas
Calculation of List of Capacities and Exhaust Gas Data

Updated engine and capacities data is available from the CEAS program on www.marine.man.eu → 'Two-Stroke' → 'CEAS Engine Calculations'.

This chapter describes the necessary auxiliary machinery capacities to be used for a nominally rated engine. The capacities given are valid for seawater cooling system and central cooling water system, respectively. For derated engine, i.e. with a specified MCR different from the nominally rated MCR point, the list of capacities will be different from the nominal capacities.

Furthermore, among others, the exhaust gas data depends on the ambient temperature conditions.

Based on examples for a derated engine, the way of how to calculate the derated capacities, freshwater production and exhaust gas amounts and temperatures will be described in details.

Nomenclature

In the following description and examples of the auxiliary machinery capacities, freshwater generator production and exhaust gas data, the below nomenclatures are used:

<table>
<thead>
<tr>
<th>Engine ratings</th>
<th>Point / Index</th>
<th>Power</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nominal MCR point</td>
<td>L₁</td>
<td>P_L₁</td>
<td>n_L₁</td>

</table>

Fig. 6.01.02: Nomenclature of coolers and volume flows, etc.

Engine configurations related to SFOC

The engine type is available in the following version only with respect to the efficiency of the turbocharger:

With high efficiency turbocharger, which is the basic design and for which the lists of capacities Section 6.03 are calculated.
List of Capacities and Cooling Water Systems

The List of Capacities contain data regarding the necessary capacities of the auxiliary machinery for the main engine only, and refer to a nominally rated engine. Complying with IMO Tier II NOx limitations.

The heat dissipation figures include 10% extra margin for overload running except for the scavenge air cooler, which is an integrated part of the diesel engine.

Cooling Water Systems

The capacities given in the tables are based on tropical ambient reference conditions and refer to engines with high efficiency/conventional turbocharger running at nominal MCR (L1) for:

- Seawater cooling system,
  See diagram, Fig. 6.02.01 and nominal capacities in Fig. 6.03.01

- Central cooling water system,
  See diagram, Fig. 6.02.02 and nominal capacities in Fig. 6.03.01

The capacities for the starting air receivers and the compressors are stated in Fig. 6.03.01.

Heat radiation and air consumption

The radiation and convection heat losses to the engine room is around 1% of the engine nominal power (kW in L1).

The air consumption is approximately 98.2% of the calculated exhaust gas amount, ie. \( M_{\text{air}} = M_{\text{exh}} \times 0.982 \).

Flanges on engine, etc.

The location of the flanges on the engine are shown in: ‘Engine pipe connections’, and the flanges are identified by reference letters stated in the ‘List of flanges’; both can be found in Chapter 5.

The diagrams use the ‘Basic symbols for piping’, whereas the symbols for instrumentation according to ‘ISO 1219-1’ and ‘ISO 1219-2’ and the instrumentation list found in Appendix A.

* For main engine arrangements with built-on power take-off (PTO) of a MAN Diesel & Turbo recommended type and/or torsional vibration damper the engine's capacities must be increased by those stated for the actual system

** ISO based

For List of Capacities for derated engines and performance data at part load please visit http://www.mandieselturbo/ceas/index.htm
Auxiliary Machinery Capacities

The dimensioning of heat exchangers (coolers) and pumps for derated engines can be calculated on the basis of the heat dissipation values found by using the following description and diagrams. Those for the nominal MCR (L1), may also be used if wanted.

The nomenclature of the basic engine ratings and coolers, etc. used in this section is shown in Fig. 6.01.01 and 6.01.02.

Cooler heat dissipations

For the specified MCR (M) the following three diagrams in Figs. 6.04.01, 6.04.02 and 6.04.03 show reduction factors for the corresponding heat dissipations for the coolers, relative to the values stated in the ‘List of Capacities’ valid for nominal MCR (L1).
The derated cooler capacities may then be found by means of following equations:

\[ Q_{\text{air}, M} = Q_{\text{air}, L1} \times \left( \frac{Q_{\text{air}} \%}{100} \right) \]
\[ Q_{\text{jw}, M} = Q_{\text{jw}, L1} \times \left( \frac{Q_{\text{jw}} \%}{100} \right) \]
\[ Q_{\text{lub}, M} = Q_{\text{lub}, L1} \times \left( \frac{Q_{\text{lub}} \%}{100} \right) \]

and for a central cooling water system the central cooler heat dissipation is:

\[ Q_{\text{cent}, M} = Q_{\text{air}, M} + Q_{\text{jw}, M} + Q_{\text{lub}, M} \]

### Pump capacities

The pump capacities given in the ‘List of Capacities’ refer to engines rated at nominal MCR (L1). For lower rated engines, a marginal saving in the pump capacities is obtainable.

To ensure proper lubrication, the lubricating oil pump must remain unchanged.

In order to ensure reliable starting, the starting air compressors and the starting air receivers must also remain unchanged.

The jacket cooling water pump capacity is relatively low. Practically no saving is possible, and it is therefore unchanged.

### Seawater cooling system

The derated seawater pump capacity is equal to the sum of the below found derated seawater flow capacities through the scaveng air and lube oil coolers, as these are connected in parallel.

The seawater flow capacity for each of the scaveng air, lube oil and jacket water coolers can be reduced proportionally to the reduced heat dissipations found in Figs. 6.04.01, 6.04.02 and 6.04.03, respectively i.e. as follows:

\[ V_{\text{sw,air}, M} = V_{\text{sw,air}, L1} \times \left( \frac{Q_{\text{air}} \%}{100} \right) \]
\[ V_{\text{sw,lub}, M} = V_{\text{sw,lub}, L1} \times \left( \frac{Q_{\text{lub}} \%}{100} \right) \]
\[ V_{\text{sw,jw}, M} = V_{\text{sw,lub}, M} \]

However, regarding the scaveng air cooler(s), the engine maker has to approve this reduction in order to avoid too low a water velocity in the scaveng air cooler pipes.

As the jacket water cooler is connected in series with the lube oil cooler, the seawater flow capacity for the latter is used also for the jacket water cooler.

### Central cooling water system

If a central cooler is used, the above still applies, but the central cooling water capacities are used instead of the above seawater capacities. The seawater flow capacity for the central cooler can be reduced in proportion to the reduction of the total cooler heat dissipation, i.e. as follows:

\[ V_{\text{cw,air}, M} = V_{\text{cw,air}, L1} \times \left( \frac{Q_{\text{air}} \%}{100} \right) \]
\[ V_{\text{cw,lub}, M} = V_{\text{cw,lub}, L1} \times \left( \frac{Q_{\text{lub}} \%}{100} \right) \]
\[ V_{\text{cw,jw}, M} = V_{\text{cw,jw}, M} \]
\[ V_{\text{sw,cent}, M} = V_{\text{sw,cent}, L1} \times \left( \frac{Q_{\text{cent}} \%}{100} \right) \]

### Pump pressures

Irrespective of the capacities selected as per the above guidelines, the below-mentioned pump heads at the mentioned maximum working temperatures for each system must be kept:

<table>
<thead>

### Flow velocities

For external pipe connections, we prescribe the following maximum velocities:

- Marine diesel oil: 1.0 m/s
- Heavy fuel oil: 0.6 m/s
- Lubricating oil: 1.8 m/s
- Cooling water: 3.0 m/s
Calculation of List of Capacities for Derated Engine

Example 1:

**Pump and cooler capacities for a** derated 6S46MC-C8.2-TII with 1 high efficiency MAN TCA55-21 turbocharger, high load, fixed pitch propeller and central cooling water system.

Nominal MCR, \( (L) \) \( P_{L1} \): 8,280 kW (100.0%) and 129.0 r/min (100.0%)

Specified MCR, \( (M) \) \( P_{M} \): 7,452 kW (90.0%) and 122.6 r/min (95.0%)

The method of calculating the reduced capacities for point M \( (n_{M\%} = 95.0\% \text{ and } P_{M\%} = 90.0\%) \) is shown below.

The values valid for the nominal rated engine are found in the 'List of Capacities', Figs. 6.03.01 and 6.03.02, and are listed together with the result in the figure on the next page.

**Heat dissipation of scavenge air cooler**

Fig. 6.04.01 which approximately indicates a \( Q_{air\%} = 87.4\% \) heat dissipation, i.e.:

\[
Q_{air,M} = Q_{air,L1} \times Q_{air\%} / 100
\]

\( Q_{air,M} = 3,490 \times 0.874 = 3,050 \text{ kW} \)

**Heat dissipation of jacket water cooler**

Fig. 6.04.02 indicates a \( Q_{jw\%} = 92.2\% \) heat dissipation; i.e.:

\[
Q_{jw,M} = Q_{jw,L1} \times Q_{jw\%} / 100
\]

\( Q_{jw,M} = 1,310 \times 0.922 = 1,208 \text{ kW} \)

**Heat dissipation of lube oil cooler**

Fig. 6.04.03 indicates a \( Q_{lub\%} = 95.8\% \) heat dissipation; i.e.:

\[
Q_{lub,M} = Q_{lub,L1} \times Q_{lub\%} / 100
\]

\( Q_{lub,M} = 700 \times 0.958 = 671 \text{ kW} \)

**Heat dissipation of central water cooler**

\[
Q_{cent,M} = Q_{air,M} + Q_{jw,M} + Q_{lub,M}
\]

\( Q_{cent,M} = 3,050 + 1,208 + 671 = 4,929 \text{ kW} \)

Total cooling water flow through scavenge air coolers:

\[
V_{cw,air,M} = V_{cw,air,L1} \times Q_{air\%} / 100
\]

\( V_{cw,air,M} = 125 \times 0.874 = 109 \text{ m}^3/\text{h} \)

Cooling water flow through lubricating oil cooler:

\[
V_{cw,lub,M} = V_{cw,lub,L1} \times Q_{lub\%} / 100
\]

\( V_{cw,lub,M} = 86 \times 0.958 = 82 \text{ m}^3/\text{h} \)

Cooling water flow through central cooler (Central cooling water pump):

\[
V_{cw,cent,M} = V_{cw,air,M} + V_{cw,lub,M}
\]

\( V_{cw,cent,M} = 109 + 82 = 191 \text{ m}^3/\text{h} \)

Cooling water flow through jacket water cooler (as for lube oil cooler):

\[
V_{cw,jw,M} = V_{cw,lub,M}
\]

\( V_{cw,jw,M} = 82 \text{ m}^3/\text{h} \)

Seawater pump for central cooler

As the seawater pump capacity and the central cooler heat dissipation for the nominal rated engine found in the 'List of Capacities' are 268 m\(^3\)/h and 5,500 kW the derated seawater pump flow equals:

Seawater pump:

\[
V_{sw,cent,M} = V_{sw,cent,L1} \times Q_{cent\%} / Q_{cent,L1}
\]

\( V_{sw,cent,M} = 268 \times 4,929 / 5,500 = 240 \text{ m}^3/\text{h} \)

The exhaust gas temperatures refer to after turbocharger
* Calculated in example 3, in this chapter
Freshwater Generator

If a freshwater generator is installed and is utilising the heat in the jacket water cooling system, it should be noted that the actual available heat in the jacket cooling water system is lower than indicated by the heat dissipation figures valid for nominal MCR (L₁) given in the List of Capacities. This is because the latter figures are used for dimensioning the jacket water cooler and hence incorporate a safety margin which can be needed when the engine is operating under conditions such as, e.g. overload. Normally, this margin is 10% at nominal MCR.

Calculation Method

For a derated diesel engine, i.e. an engine having a specified MCR (M) different from L₁, the relative jacket water heat dissipation for point M may be found, as previously described, by means of Fig. 6.04.02.

At part load operation, the actual jacket water heat dissipation will be reduced according to the curves for fixed pitch propeller (FPP) or for constant speed, controllable pitch propeller (CPP), respectively, in Fig. 6.04.04.

With reference to the above, the heat actually available for a derated diesel engine may then be found as follows:

1. Engine power equal to specified power M.

   For specified MCR (M) the diagram Fig. 6.04.02 is to be used, i.e. giving the percentage correction factor ‘Qjw%’ and hence for specified MCR power Pₘ:
   \[ Q_{jw,M} = Q_{jw,L1} \times \frac{Q_{jw}}{100} \times 0.9 \ (0.88) \]  

2. Engine power lower than specified MCR power.

   For powers lower than the specified MCR power, the value Qₘ found for point M by means of the above equation [1] is to be multiplied by the correction factor kₚ found in Fig. 6.04.04 and hence
   \[ Q_{jw} = Q_{jw,M} \times k_p \ -15\%/0\% \]  

where
- Qₘ = jacket water heat dissipation
- Qₘ,L₁ = jacket water heat dissipation at nominal MCR (L₁)
- Qₘ% = percentage correction factor from Fig. 6.04.02
- Qₘ,M = jacket water heat dissipation at specified MCR power (M), found by means of equation [1]
- kₚ = part load correction factor from Fig. 6.04.04
- 0.9 = factor for safety margin of cooler, tropical ambient conditions

The heat dissipation is assumed to be more or less independent of the ambient temperature conditions, yet the safety margin/ambient condition factor of about 0.88 instead of 0.90 will be more accurate for ambient conditions corresponding to ISO temperatures or lower. The heat dissipation tolerance from -15% to 0% stated above is based on experience.
Jacket Cooling Water Temperature Control

When using a normal freshwater generator of the single-effect vacuum evaporator type, the freshwater production - based on the available jacket cooling water heat $Q_{jw}$ - may, for guidance, be estimated as 0.03 t/24h per 1 kW heat, i.e.:

$$M_{fw} = 0.03 \times Q_{jw} \text{ t/24h} -15\% / 0\% \quad [3]$$

where

- $M_{fw}$ is the freshwater production in tons per 24 hours
- $Q_{jw}$ is to be stated in kW

If necessary, all the actually available jacket cooling water heat may be used provided that a special temperature control system ensures that the jacket cooling water temperature at the outlet from the engine does not fall below a certain level. Such a temperature control system may consist, e.g., of a special by-pass pipe installed in the jacket cooling water system, see Fig. 6.04.05, or a special built-in temperature control in the freshwater generator, e.g., an automatic start/stop function, or similar.

If such a special temperature control is not applied, we recommend limiting the heat utilised to maximum 50% of the heat actually available at specified MCR, and only using the freshwater generator at engine loads above 50%. Considering the cooler margin of 10% and the minus tolerance of -15%, this heat corresponds to $50 \times (1.00 - 0.15) \times 0.9 = 38\%$ of the jacket water cooler capacity $Q_{jw,M}$ used for dimensioning of the jacket water cooler.

Valve A: ensures that $T_{jw} < 80\, ^\circ C$
Valve B: ensures that $T_{jw} > 80 - 5\, ^\circ C = 75\, ^\circ C$
Valve B and the corresponding by-pass may be omitted if, for example, the freshwater generator is equipped with an automatic start/stop function for too low jacket cooling water temperature.

If necessary, all the actually available jacket cooling water heat may be utilised provided that a special temperature control system ensures that the jacket cooling water temperature at the outlet from the engine does not fall below a certain level.

Fig. 6.04.05: Freshwater generators. Jacket cooling water heat recovery flow diagram
Calculation of Freshwater Production for Derated Engine

Example 2:

Freshwater production from a derated 6S46MC-C8.2-TII with 1 high efficiency MAN TCA55-21 turbocharger, high load and fixed pitch propeller.

Based on the engine ratings below, this example will show how to calculate the expected available jacket cooling water heat removed from the diesel engine, together with the corresponding freshwater production from a freshwater generator.

The calculation is made for the service rating (S) of the diesel engine being 80% of the specified MCR.

Nominal MCR, (L)  \( P_{L1} : 8,280 \text{ kW (100.0%) and 129.0 r/min (100.0%)} \)

Specified MCR, (M)  \( P_{M} : 7,452 \text{ kW (90.0%) and 122.6 r/min (95.0%)} \)

Service rating, (S)  \( P_{S} : 5,961 \text{ kW and 113.8 r/min, } P_{S} = 80.0\% \text{ of } P_{M} \)

Reference conditions

- Air temperature \( T_{\text{air}} \) .............................................................. 20° C
- Scavenge air coolant temperature \( T_{\text{CW}} \) ........................................... 18° C
- Barometric pressure \( p_{\text{bar}} \) ...................................................... 1,013 mbar
- Exhaust gas back-pressure at specified MCR \( \Delta p_{M} \) ............. 300 mm WC

The expected available jacket cooling water heat at service rating is found as follows:

\[
Q_{jw,L1} = 1,310 \text{ kW from List of Capacities}
\]

\[
Q_{jw\%} = 92.2\% \text{ using } 90.0\% \text{ power and } 95.0\% \text{ speed for } M \text{ in Fig. 6.04.02}
\]

By means of equation [1], and using factor 0.885 for actual ambient condition the heat dissipation in the SMCR point (M) is found:

\[
Q_{jw,M} = Q_{jw,L1} \times \frac{Q_{jw\%}}{100} \times 0.885 = 1,310 \times \frac{92.2}{100} \times 0.885 = 1,069 \text{ kW}
\]

For the service point the corresponding expected obtainable freshwater production from a freshwater generator of the single effect vacuum evaporator type is then found from equation [3]:

\[
M_{fw} = 0.03 \times Q_{jw} = 0.03 \times 911 = 27.4 \text{ t/24h}
\]

-15%/0%}

By means of equation [2], the heat dissipation in the service point (S) i.e. for 80.0% of specified MCR power, is found:

\[
k_p = 0.852 \text{ using } 80.0\% \text{ in Fig. 6.04.04}
\]

\[
Q_{jw} = Q_{jw,M} \times k_p = 1,069 \times 0.852 = 911 \text{ kW}
\]

-15%/0%
Exhaust Gas Amount and Temperature

Influencing factors

The exhaust gas data to be expected in practice depends, primarily, on the following three factors:

a) The specified MCR point of the engine (point M):

\[ P_M : \text{power in kW at specified MCR point} \]
\[ n_M : \text{speed in r/min at specified MCR point} \]

b) The ambient conditions, and exhaust gas back-pressure:

\[ T_{\text{air}} : \text{actual ambient air temperature, in } ^{\circ}\text{C} \]
\[ P_{\text{bar}} : \text{actual barometric pressure, in mbar} \]
\[ T_{\text{CW}} : \text{actual scavenge air coolant temperature, in } ^{\circ}\text{C} \]
\[ \Delta p_M : \text{exhaust gas back-pressure in mm WC at specified MCR} \]

b) The ambient conditions, and exhaust gas back-pressure:

\[ T_{\text{air}} : \text{actual ambient air temperature, in } ^{\circ}\text{C} \]
\[ P_{\text{bar}} : \text{actual barometric pressure, in mbar} \]
\[ T_{\text{CW}} : \text{actual scavenge air coolant temperature, in } ^{\circ}\text{C} \]
\[ \Delta p_M : \text{exhaust gas back-pressure in mm WC at specified MCR} \]

b) The ambient conditions, and exhaust gas back-pressure:

\[ T_{\text{air}} : \text{actual ambient air temperature, in } ^{\circ}\text{C} \]
\[ P_{\text{bar}} : \text{actual barometric pressure, in mbar} \]
\[ T_{\text{CW}} : \text{actual scavenge air coolant temperature, in } ^{\circ}\text{C} \]
\[ \Delta p_M : \text{exhaust gas back-pressure in mm WC at specified MCR} \]

Calculation Method

To enable the project engineer to estimate the actual exhaust gas data at an arbitrary service rating, the following method of calculation may be used.

The partial calculations based on the above influencing factors have been summarised in equations [4] and [5].

\[ M_{\text{exh}} : \text{exhaust gas amount in kg/h, to be found} \]
\[ T_{\text{exh}} : \text{exhaust gas temperature in } ^{\circ}\text{C, to be found} \]

\[ M_{\text{exh}} = M_{L1} \times \frac{P_M}{P_{L1}} \times \left( 1 + \frac{\Delta m_{\text{amb}}}{100} \right) \times \left( 1 + \frac{\Delta M_{\text{amb}}}{100} \right) \times \left( 1 + \frac{\Delta m_{\text{amb}}}{100} \right) \times P_{S1} \times 100 \text{ kg/h +/-5% } [4] \]

\[ T_{\text{exh}} = T_{L1} + \Delta T_M + \Delta T_{\text{amb}} + \Delta T_S \text{ } ^{\circ}\text{C } -15^\circ \text{C} \text{ to } +15^\circ \text{C } [5] \]

where, according to ‘List of capacities’, i.e. referring to ISO ambient conditions and 300 mm WC back-pressure and specified in L:

\[ M_{L1} : \text{exhaust gas amount in kg/h at nominal MCR (L)} \]
\[ T_{L1} : \text{exhaust gas temperature after turbocharger in } ^{\circ}\text{C at nominal MCR (L)} \]

The partial calculations based on the influencing factors are described in the following:

a) Correction for choice of specified MCR point

When choosing a specified MCR point ‘M’ other than the nominal MCR point ‘L’, the resulting changes in specific exhaust gas amount and temperature are found by using as input in diagrams the corresponding percentage values (of L) for specified MCR power \( P_{Mx} \) and speed \( n_{Mx} \):

\[ P_{Mx} = \frac{P_M}{P_{L1}} \times 100\% \]
\[ n_{Mx} = \frac{n_M}{n_{L1}} \times 100\% \]

Fig. 6.04.06: Summarising equations for exhaust gas amounts and temperatures
Δm_M% = 14 × ln (P_M/P_L1) – 24 × ln (n_M/n_L1)

Fig. 6.04.07: Change of specific exhaust gas amount, Δm_M% in % of L1 value

Δm_M% : change of specific exhaust gas amount, in % of specific gas amount at nominal MCR (L1), see Fig. 6.04.07.

ΔT_M : change in exhaust gas temperature after turbocharger relative to the L1 value, in °C, see Fig. 6.04.08. (P_O = P_M)

ΔT_M = 15 × ln (P_M/P_L1) + 45 × ln (n_M/n_L1)

Fig. 6.04.08: Change of exhaust gas temperature, ΔT_M in point M, in °C after turbocharger relative to L1 value

b) Correction for actual ambient conditions and back-pressure

For ambient conditions other than ISO 3046-1:2002 (E) and ISO 15550:2002 (E), and back-pressure other than 300 mm WC at specified MCR point (M), the correction factors stated in the table in Fig. 6.04.09 may be used as a guide, and the corresponding relative change in the exhaust gas data may be found from equations [7] and [8], shown in Fig. 6.04.10.

Fig. 6.04.09: Correction of exhaust gas data for ambient conditions and exhaust gas back pressure
\[ \Delta M_{\text{amb}}(\%) = -0.41 \times (T_{\text{air}} - 25) + 0.03 \times (p_{\text{bar}} - 1000) + 0.19 \times (T_{\text{CW}} - 25) - 0.011 \times (\Delta p_{M} - 300) \% \]  
\[ \Delta T_{\text{amb}} = 1.6 \times (T_{\text{air}} - 25) - 0.01 \times (p_{\text{bar}} - 1000) + 0.1 \times (T_{\text{CW}} - 25) + 0.05 \times (\Delta p_{M} - 300) \degree C \]  

where the following nomenclature is used:

- \( \Delta M_{\text{amb}}(\%) \): change in exhaust gas amount, in % of amount at ISO conditions
- \( \Delta T_{\text{amb}} \): change in exhaust gas temperature, in °C compared with temperatures at ISO conditions

**Fig. 6.04.10:** Exhaust gas correction formula for ambient conditions and exhaust gas back pressure

\[ P_{S\%} = (P_{S}/P_{M}) \times 100\% \]
\[ \Delta m_{\%} = 37 \times (P_{S}/P_{M})^3 - 87 \times (P_{S}/P_{M})^2 + 31 \times (P_{S}/P_{M}) + 19 \]

**Fig. 6.04.11:** Change of specific exhaust gas amount, \( \Delta m_{\%} \), in % at part load, and valid for FPP and CPP

\[ P_{S\%} = (P_{S}/P_{M}) \times 100\% \]
\[ \Delta T_{s} = 280 \times (P_{S}/P_{M})^2 - 410 \times (P_{S}/P_{M}) + 130 \]

**Fig. 6.04.12:** Change of exhaust gas temperature, \( \Delta T_{s} \), in °C at part load, and valid for FPP and CPP

**c) Correction for engine load**

Figs. 6.04.11 and 6.04.12 may be used, as guidance, to determine the relative changes in the specific exhaust gas data when running at part load, compared to the values in the specified MCR point, i.e. using as input \( P_{S\%} = (P_{S}/P_{M}) \times 100\% \):

- \( \Delta m_{\%} \): change in specific exhaust gas amount, in % of specific amount at specified MCR point, see Fig. 6.04.11.
- \( \Delta T_{s} \): change in exhaust gas temperature, in °C, see Fig. 6.04.12.
Calculation of Exhaust Data for Derated Engine

Example 3:

Expected exhaust gas data for a derated 6S46MC-C8.2-TII with 1 high efficiency MAN TCA55-21 turbocharger, high load and fixed pitch propeller.

Based on the engine ratings below, and by means of an example, this chapter will show how to calculate the expected exhaust gas amount and temperature at service rating, and for a given ambient reference condition different from ISO.

The calculation is made for the service rating (S) of the diesel engine being 80% of the specified MCR.

Nominal MCR, (L) \( P_{L1} \): 8,280 kW (100.0%) and 129.0 r/min (100.0%)
Specified MCR, (M) \( P_{M} \): 7,452 kW (90.0%) and 122.6 r/min (95.0%)
Service rating, (S) \( P_{S} \): 5,961 kW and 113.8 r/min, \( P_{S} = 80.0\% \) of \( P_{M} \)

Reference conditions
\( T_{air} \) .............................................................. 20° C
\( T_{CW} \) ....................................................... 18° C
\( p_{bar} \) ...................................................... 1,013 mbar
Exhaust gas back-pressure at specified MCR \( \Delta p_{M} \) ............ 300 mm WC

a) Correction for choice of specified MCR point M:
\( P_{M\%} = \frac{7,452}{8,280} \times 100 = 90.0\% \)
\( n_{M\%} = \frac{122.6}{129.0} \times 100 = 95.0\% \)

By means of Figs. 6.04.07 and 6.04.08:
\( \Delta m_{M\%} = -0.25\% \)
\( \Delta T_{M} = -3.9 ^{\circ} C \)

b) Correction for ambient conditions and back-pressure:

By means of equations [7] and [8]:
\( \Delta M_{amb\%} = -0.41 \times (20 - 25) + 0.03 \times (1,013 - 1,000) \\
+ 0.19 \times (18 - 25) - 0.011 \times (300 - 300)\% \)

\( \Delta T_{amb} = 1.6 \times (20 - 25) - 0.01 \times (1,013 - 1,000) \\
+ 0.05 \times (300 - 300) ^{\circ} C \)
\( \Delta T_{amb} = - 8.8 ^{\circ} C \)

By means of Figs. 6.04.11 and 6.04.12:
\( \Delta m_{S\%} = + 7.1\% \)
\( \Delta T_{S} = - 18.8 ^{\circ} C \)

Service rating = 80% of specified MCR power
Final calculation

By means of equations [4] and [5], the final result is found taking the exhaust gas flow $M_{\text{exh}}$ and temperature $T_{\text{exh}}$ from the ‘List of Capacities’:

\[
M_{\text{L1}} = 71,000 \text{ kg/h}
\]
\[
M_{\text{exh}} = 71,000 \times \frac{7.452}{8.280} \times (1 + \frac{-0.25}{100}) \times (1 + \frac{1.11}{100}) \times (1 + \frac{7.1}{100}) \times \frac{80}{100} = 55,219 \text{ kg/h}
\]
\[
M_{\text{exh}} = 55,200 \text{ kg/h} \pm 15\%
\]

The exhaust gas temperature

\[
T_{\text{L1}} = 240 \degree C
\]
\[
T_{\text{exh}} = 240 - 3.9 - 8.8 - 18.8 = 208.5 \degree C
\]
\[
T_{\text{exh}} = 208.5 \degree C \pm 5 \degree C
\]

Exhaust gas data at specified MCR (ISO)

At specified MCR (M), the running point may be in equations [4] and [5] considered as a service point where $P_{\text{S/k}} = 100$, $\Delta m_{\text{S/k}} = 0.0$ and $\Delta T_s = 0.0$.

For ISO ambient reference conditions where $\Delta M_{\text{amb}/%} = 0.0$ and $\Delta T_{\text{amb}} = 0.0$, the corresponding calculations will be as follows:

\[
M_{\text{exh,M}} = 71,000 \times \frac{7.452}{8.280} \times (1 + \frac{-0.25}{100}) \times (1 + \frac{0.0}{100}) \times (1 + \frac{0.0}{100}) \times \frac{80}{100} = 63,731 \text{ kg/h}
\]
\[
M_{\text{exh,M}} = 63,700 \text{ kg/h} \pm 15\%
\]

The exhaust gas temperature

\[
T_{\text{exh,M}} = 240 - 3.9 + 0 + 0 = 236.1 \degree C
\]
\[
T_{\text{exh,M}} = 236.1 \degree C \pm 5 \degree C
\]

The air consumption will be:

\[
63,731 \times 0.982 \text{ kg/h} = 62,584 \text{ kg/h} \lesssim \lesssim 62,584 / 3,600 \text{ kg/s} = 17.4 \text{ kg/s}
\]
Pressurised Fuel Oil System

The system is so arranged that both diesel oil and heavy fuel oil can be used, see figure 7.01.02.

From the service tank the fuel is led to an electrically driven supply pump by means of which a pressure of approximately 4 bar can be maintained in the low pressure part of the fuel circulating system, thus avoiding gasification of the fuel in the venting box in the temperature ranges applied.

The venting box is connected to the service tank via an automatic deaerating valve, which will release any gases present, but will retain liquids.

From the low pressure part of the fuel system the fuel oil is led to an electrically-driven circulating pump, which pumps the fuel oil through a heater and a full flow filter situated immediately before the inlet to the engine.

An in-line viscosity regulator located after the heater controls the heating temperature according to the prescribed viscosity of the specific fuel oil.

Design parameters

To ensure ample filling of the fuel injection pumps, the capacity of the electrically-driven circulating pump is higher than the amount of fuel consumed by the diesel engine. Surplus fuel oil is recirculated from the engine through the venting box.

To ensure a constant fuel pressure to the fuel injection pumps during all engine loads, a spring loaded overflow valve is inserted in the fuel oil system on the engine.

The fuel oil pressure measured on the engine (at fuel pump level) should be 7-8 bar, equivalent to a circulating pump pressure of 10 bar.

The built-on overflow valves, if any, at the supply pumps are to be adjusted to 5 bar, whereas the external bypass valve is adjusted to 4 bar. The pipes between the tanks and the supply pumps shall have minimum 50% larger passage area than the pipe between the supply pump and the circulating pump.

If the fuel oil pipe ‘X’ at inlet to engine is made as a straight line immediately at the end of the engine, it will be necessary to mount an expansion joint. If the connection is made as indicated, with a bend immediately at the end of the engine, no expansion joint is required.

Fuel Pumps and Drain

The introduction of the pump sealing arrangement, the so-called 'umbrella' type, has made it possible to omit the separate camshaft lubricating oil system.

The umbrella type fuel oil pump has an additional external leakage rate of clean fuel oil which, through ‘AF’, is led to a tank and can be pumped to the heavy fuel oil service tank or settling tank.

The flow rate in litres is approximately as listed in Table 7.01.01.

<table>
<thead>
<tr>
<th>Engine</th>
<th>Flow rate, litres/cyl. h</th>

</thead>
<tbody>
<tr>
<td>S50MC-C, S46MC-C</td>
<td>0.50</td>
</tr>
</tbody>
</table>

*Table 7.01.01: Approximate flow in HCU leakage drain.*

This drained clean oil will, of course, influence the measured SFOC, but the oil is thus not wasted, and the quantity is well within the measuring accuracy of the flowmeters normally used.

The main purpose of the drain ‘AF’ is to collect pure fuel oil from the fuel pumps as well as the unintentional leakage from the high pressure pipes. The drain oil is lead to a tank and can be pumped to the Heavy Fuel Oil service tank or to the settling tank.

The ‘AF’ drain is provided with a box for giving alarm in case of leakage in a high pressure pipes.
The size of the sludge tank is determined on the basis of the draining intervals, the classification society rules, and on whether it may be vented directly to the engine room.

Drain ‘AF’ is shown in Fig. 7.03.01.

The main components of the pressurised fuel oil system are further explained in section 7.05.

Fuel Oil System

The letters refer to the list of ‘Counterflanges’

Fig. 7.01.02: Fuel oil system
Fuel Considerations

When the engine is stopped, the circulating pump will continue to circulate heated heavy fuel through the fuel oil system on the engine, thereby keeping the fuel pumps heated and the fuel valves deaerated. This automatic circulation of preheated fuel during engine standstill is the background for our recommendation: constant operation on heavy fuel.

In addition, if this recommendation was not followed, there would be a latent risk of diesel oil and heavy fuels of marginal quality forming incompatible blends during fuel change over or when operating in areas with restrictions on sulphur content in fuel oil due to exhaust gas emission control.

In special circumstances a change-over to diesel oil may become necessary – and this can be performed at any time, even when the engine is not running. Such a change-over may become necessary if, for instance, the vessel is expected to be inactive for a prolonged period with cold engine e.g. due to:

- docking
- stop for more than five days
- major repairs of the fuel system, etc.

Heating of fuel drain pipe

Owing to the relatively high viscosity of the heavy fuel oil, it is recommended that the drain pipe and the fuel oil drain tank are heated to min. 50 °C, but max. 100 °C.

The drain pipe between engine and tank can be heated by the jacket water, as shown in Fig. 7.01.02 ‘Fuel oil system’ as flange ‘BD’.

Fuel flow velocity and viscosity

For external pipe connections, we prescribe the following maximum flow velocities:

- Marine diesel oil ............................................... 1.0 m/s
- Heavy fuel oil ..................................................... 0.6 m/s

The fuel viscosity is influenced by factors such as emulsification of water into the fuel for reducing the NOx emission. This is further described in Section 7.06.

An emulsification arrangement for the main engine is described in our publication:

Exhaust Gas Emission Control Today and Tomorrow

Further information about fuel oil specifications is available in our publication:

Guidelines for Fuels and Lubes Purchasing

**Fuel Oils**

**Marine diesel oil:**
- Marine diesel oil ISO 8217, Class DMB
- British Standard 6843, Class DMB
- Similar oils may also be used

**Heavy fuel oil (HFO)**

Most commercially available HFO with a viscosity below 700 cSt at 50 °C (7,000 sec. Redwood I at 100 °F) can be used.

For guidance on purchase, reference is made to ISO 8217:2012, British Standard 6843 and to CIMAC recommendations regarding requirements for heavy fuel for diesel engines, fourth edition 2003, in which the maximum acceptable grades are RMH 700 and RMK 700. The above-mentioned ISO and BS standards supersede BSMA 100 in which the limit was M9.

The data in the above HFO standards and specifications refer to fuel as delivered to the ship, i.e. before on-board cleaning.

In order to ensure effective and sufficient cleaning of the HFO, i.e. removal of water and solid contaminants, the fuel oil specific gravity at 15 °C (60 °F) should be below 0.991, unless modern types of centrifuges with adequate cleaning abilities are used.

Higher densities can be allowed if special treatment systems are installed.

Current analysis information is not sufficient for estimating the combustion properties of the oil. This means that service results depend on oil properties which cannot be known beforehand. This especially applies to the tendency of the oil to form deposits in combustion chambers, gas passages and turbines. It may, therefore, be necessary to rule out some oils that cause difficulties.

**Guiding heavy fuel oil specification**

Based on our general service experience we have, as a supplement to the above mentioned standards, drawn up the guiding HFO specification shown below.

Heavy fuel oils limited by this specification have, to the extent of the commercial availability, been used with satisfactory results on MAN B&W two-stroke low speed diesel engines.

The data refers to the fuel as supplied i.e. before any on-board cleaning.

*Provided automatic clarifiers are installed

m/m = mass  v/v = volume

If heavy fuel oils with analysis data exceeding the above figures are to be used, especially with regard to viscosity and specific gravity, the engine builder should be contacted for advice regarding possible fuel oil system changes.
Fuel Oil Pipes and Drain Pipes

The letters refer to list of ‘Counterflanges’

The item No. refer to ‘Guidance values automation’

Fig. 7.03.01: Fuel oil and drain pipes, standard fuel pump
Fuel Oil Pipe Insulation

Insulation of fuel oil pipes and fuel oil drain pipes should not be carried out until the piping systems have been subjected to the pressure tests specified and approved by the respective classification society and/or authorities, Fig. 7.04.01.

The directions mentioned below include insulation of hot pipes, flanges and valves with a surface temperature of the complete insulation of maximum 55 °C at a room temperature of maximum 38 °C. As for the choice of material and, if required, approval for the specific purpose, reference is made to the respective classification society.

Fuel oil pipes

The pipes are to be insulated with 20 mm mineral wool of minimum 150 kg/m³ and covered with glass cloth of minimum 400 g/m².

Fuel oil pipes and heating pipes together

Two or more pipes can be insulated with 30 mm wired mats of mineral wool of minimum 150 kg/m³ covered with glass cloth of minimum 400 g/m².

Flanges and valves

The flanges and valves are to be insulated by means of removable pads. Flange and valve pads are made of glass cloth, minimum 400 g/m², containing mineral wool stuffed to minimum 150 kg/m³.

Thickness of the pads to be:

Fuel oil pipes .................................................. 20 mm
Fuel oil pipes and heating pipes together.... 30 mm

The pads are to be fitted so that they lap over the pipe insulating material by the pad thickness. At flanged joints, insulating material on pipes should not be fitted closer than corresponding to the minimum bolt length.

Mounting

Mounting of the insulation is to be carried out in accordance with the supplier’s instructions.

Fig. 7.04.01: Details of fuel oil pipes insulation, option: 435 121. Example from 98-50 MC engine

178 50 60-2.0
Fuel Oil Pipe Heat Tracing

The steam tracing of the fuel oil pipes is intended to operate in two situations:

1. When the circulation pump is running, there will be a temperature loss in the piping, see Fig. 7.04.02. This loss is very small, therefore tracing in this situation is only necessary with very long fuel supply lines.

2. When the circulation pump is stopped with heavy fuel oil in the piping and the pipes have cooled down to engine room temperature, as it is not possible to pump the heavy fuel oil. In this situation the fuel oil must be heated to pumping temperature of about 50 °C.

To heat the pipe to pumping level we recommend to use 100 watt leaking/meter pipe.

Fuel Oil and Lubricating Oil Pipe Spray Shields

In order to fulfil IMO regulations, fuel oil and lubricating oil pipe assemblies are to be enclosed by spray shields as shown in Fig. 7.04.04a and b.

To avoid leaks, the spray shields are to be installed after pressure testing of the pipe system.
Components for Fuel Oil System

Fuel oil centrifuges

The manual cleaning type of centrifuges are not to be recommended. Centrifuges must be self-cleaning, either with total discharge or with partial discharge.

Distinction must be made between installations for:

- Specific gravities < 0.991 (corresponding to ISO 8217 and British Standard 6843 from RMA to RMH, and CIMAC from A to H-grades)
- Specific gravities > 0.991 and (corresponding to CIMAC K-grades).

For the latter specific gravities, the manufacturers have developed special types of centrifuges, e.g.:

- Alfa Laval
- Westfalia
- Mitsubishi
- Alcap
- Unitrol
- E-Hidens II

The centrifuge should be able to treat approximately the following quantity of oil:

0.23 litres/kWh

This figure includes a margin for:

- Water content in fuel oil
- Possible sludge, ash and other impurities in the fuel oil
- Increased fuel oil consumption, in connection with other conditions than ISO standard condition
- Purifier service for cleaning and maintenance.

The size of the centrifuge has to be chosen according to the supplier’s table valid for the selected viscosity of the Heavy Fuel Oil. Normally, two centrifuges are installed for Heavy Fuel Oil (HFO), each with adequate capacity to comply with the above recommendation.

A centrifuge for Marine Diesel Oil (MDO) is not a must. However, MAN Diesel & Turbo recommends that at least one of the HFO purifiers can also treat MDO.

If it is decided after all to install an individual purifier for MDO on board, the capacity should be based on the above recommendation, or it should be a centrifuge of the same size as that for HFO.

The Nominal MCR is used to determine the total installed capacity. Any derating can be taken into consideration in border-line cases where the centrifuge that is one step smaller is able to cover Specified MCR.

Fuel oil supply pump

This is to be of the screw or gear wheel type.

Fuel oil viscosity, specified up to 700 cSt at 50 °C
Fuel oil viscosity maximum up to 1,000 cSt
Pump head up to 4 bar
Fuel oil flow up to 1,000 cSt
Delivery pressure up to 4 bar
Working temperature up to 100 °C
Minimum temperature up to 50 °C

The capacity stated in ‘List of Capacities’ is to be fulfilled with a tolerance of: +0% to +15% and shall also be able to cover the back-flushing, see ‘Fuel oil filter’.

Fuel oil circulating pump

This is to be of the screw or gear wheel type.

Fuel oil viscosity, specified up to 700 cSt at 50 °C
Fuel oil viscosity normal up to 20 cSt
Fuel oil viscosity maximum up to 1,000 cSt
Fuel oil flow up to 1,000 cSt
Pump head up to 6 bar
Delivery pressure up to 10 bar
Working temperature up to 150 °C

The capacity stated in ‘List of Capacities’ is to be fulfilled with a tolerance of: +0% to +15% and shall also be able to cover the back-flushing, see ‘Fuel oil filter’.

Pump head is based on a total pressure drop in filter and preheater of maximum 1.5 bar.
Fuel Oil Heater

The heater is to be of the tube or plate heat exchanger type.

The required heating temperature for different oil viscosities will appear from the ‘Fuel oil heating chart’, Fig. 7.05.01. The chart is based on information from oil suppliers regarding typical marine fuels with viscosity index 70-80.

Since the viscosity after the heater is the controlled parameter, the heating temperature may vary, depending on the viscosity and viscosity index of the fuel.

Recommended viscosity meter setting is 10-15 cSt.

Fuel oil viscosity specified ... up to 700 cSt at 50°C
Fuel oil flow ........................................ see capacity of fuel oil circulating pump
Heat dissipation ...................... see ‘List of Capacities’
Pressure drop on fuel oil side .......... maximum 1 bar
Working pressure ................................ 10 bar
Fuel oil inlet temperature .............. approx. 100 °C
Fuel oil outlet temperature ................... 150 °C
Steam supply, saturated .................. 7 bar abs

To maintain a correct and constant viscosity of the fuel oil at the inlet to the main engine, the steam supply shall be automatically controlled, usually based on a pneumatic or an electrically controlled system.

Approximate viscosity after heater

![Fuel oil heating chart](image-url)
Fuel oil filter

The filter can be of the manually cleaned duplex type or an automatic filter with a manually cleaned bypass filter.

If a **double filter** (duplex) is installed, it should have sufficient capacity to allow the specified full amount of oil to flow through each side of the filter at a given working temperature with a max. 0.3 bar pressure drop across the filter (clean filter).

If a **filter with backflushing** arrangement is installed, the following should be noted. The required oil flow specified in the 'List of capacities', i.e. the delivery rate of the fuel oil supply pump and the fuel oil circulating pump, should be increased by the amount of oil used for the backflushing, so that the fuel oil pressure at the inlet to the main engine can be maintained during cleaning.

In those cases where an **automatically cleaned filter** is installed, it should be noted that in order to activate the cleaning process, certain makers of filters require a greater oil pressure at the inlet to the filter than the pump pressure specified. Therefore, the pump capacity should be adequate for this purpose, too.

The fuel oil filter should be based on heavy fuel oil of: 130 cSt at 80 °C = 700 cSt at 50 °C = 7000 sec Redwood I/100 °F.

Fuel oil flow ......................... see ‘List of capacities’

Working pressure ............................................. 10 bar

Test pressure .................. according to class rule

Absolute fineness .............................................. 50 μm

Working temperature .................. maximum 150 °C

Oil viscosity at working temperature ............ 15 cSt

Pressure drop at clean filter ................. maximum 0.3 bar

Filter to be cleaned at a pressure drop of ......................... maximum 0.5 bar

Note:

*Absolute fineness corresponds to a nominal fineness of approximately 35 μm at a retaining rate of 90%.*

The filter housing shall be fitted with a steam jacket for heat tracing.

Fuel oil venting box

The design of the Fuel oil venting box is shown in Fig. 7.05.02. The size is chosen according to the maximum flow of the fuel oil circulation pump, which is listed in section 6.03.

* The maximum flow of the fuel oil circulation pump

**Flushing of the fuel oil system**

Before starting the engine for the first time, the system on board has to be flushed in accordance with MAN Diesel & Turbo's recommendations 'Flushing of Fuel Oil System' which is available on request.
Water In Fuel Emulsification

The emulsification of water into the fuel oil reduces the NOx emission with about 1% per 1% water added to the fuel up to about 20% without modification of the engine fuel injection equipment.

A Water In Fuel emulsion (WIF) mixed for this purpose and based on Heavy Fuel Oil (HFO) is stable for a long time, whereas a WIF based on Marine Diesel Oil is only stable for a short period of time unless an emulsifying agent is applied.

As both the MAN B&W two-stroke main engine and the MAN GenSets are designed to run on emulsified HFO, it can be used for a common system.

It is supposed below, that both the main engine and GenSets are running on the same fuel, either HFO or a homogenised HFO-based WIF.

Special arrangements are available on request for a more sophisticated system in which the GenSets can run with or without a homogenised HFO-based WIF, if the main engine is running on that.

Please note that the fuel pump injection capacity shall be confirmed for the main engine as well as the GenSets for the selected percentage of water in the WIF.

Temperature and pressure

When water is added by emulsification, the fuel viscosity increases. In order to keep the injection viscosity at 10-15 cSt and still be able to operate on up to 700 cSt fuel oil, the heating temperature has to be increased to about 170 °C depending on the water content.

The higher temperature calls for a higher pressure to prevent cavitation and steam formation in the system. The inlet pressure is thus set to 13 bar.

In order to avoid temperature chock when mixing water into the fuel in the homogeniser, the water inlet temperature is to be set to 70-90 °C.

Safety system

In case the pressure in the fuel oil line drops, the water homogenised into the Water In Fuel emulsion will evaporate, damaging the emulsion and creating supply problems. This situation is avoided by installing a third, air driven supply pump, which keeps the pressure as long as air is left in the tank ‘S’, see Fig. 7.06.01.

Before the tank ‘S’ is empty, an alarm is given and the drain valve is opened, which will drain off the WIF and replace it with HFO or diesel oil from the service tank.

The drain system is kept at atmospheric pressure, so the water will evaporate when the hot emulsion enters the safety tank. The safety tank shall be designed accordingly.

Impact on the auxiliary systems

Please note that if the engine operates on Water In Fuel emulsion (WIF), in order to reduce the NOx emission, the exhaust gas temperature will decrease due to the reduced air / exhaust gas ratio and the increased specific heat of the exhaust gas.

Depending on the water content, this will have an impact on the calculation and design of the following items:
- Freshwater generators
- Energy for production of freshwater
- Jacket water system
- Waste heat recovery system
- Exhaust gas boiler
- Storage tank for freshwater

For further information about emulsification of water into the fuel and use of Water In Fuel emulsion (WIF), please refer to our publication titled:

Exhaust Gas Emission Control Today and Tomorrow

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'
Fig. 7.06.01: System for emulsification of water into the fuel common to the main engine and MAN GenSets
Lubricating Oil
Lubricating and Cooling Oil System

The lubricating oil is pumped from a bottom tank by means of the main lubricating oil pump to the lubricating oil cooler, a thermostatic valve and, through a full-flow filter, to the engine inlet RU, Fig. 8.01.01.

RU lubricates main bearings, thrust bearing, axial vibration damper, crankpin bearings, piston cooling, crosshead, camshaft and turbocharger bearings.

The main lube oil system is common to the camshaft as well. The major part of the oil is divided between piston cooling and crosshead lubrication.

From the engine, the oil collects in the oil pan, from where it is drained off to the bottom tank, see Fig. 8.06.01a and b ‘Lubricating oil tank, with cofferdam’. By class demand, a cofferdam must be placed underneath the lubricating oil tank.

The engine crankcase is vented through ‘AR’ by a pipe which extends directly to the deck. This pipe has a drain arrangement so that oil condensed in the pipe can be led to a drain tank, see details in Fig. 8.07.01.

Drains from the engine bedplate ‘AE’ are fitted on both sides, see Fig. 8.07.02 ‘Bedplate drain pipes’.

For external pipe connections, we prescribe a maximum oil velocity of 1.8 m/s.

Lubrication of turbochargers

Turbochargers with slide bearings are normally lubricated from the main engine system. AB is outlet from the turbocharger, see Figs. 8.03.01 to 8.03.03.

Figs. 8.03.01 to 8.03.03 show the lube oil pipe arrangements for different turbocharger makes.

Lubricating Oil Consumption, Centrifuges and List of Lubricating Oils

Lubricating oil consumption

The system oil consumption varies for different engine sizes and operational patterns. Typical consumptions are in the range from

*negligible to 0.1 g/kWh*

subject to load, maintenance condition and installed equipment like PTO.

Lubricating oil centrifuges

Automatic centrifuges are to be used, either with total discharge or partial discharge.

The nominal capacity of the centrifuge is to be according to the supplier’s recommendation for lubricating oil, based on the figure:

*0.136 litre/kWh*

The Nominal MCR is used as the total installed power.

Further information about lubricating oil qualities is available in our publication:

*Guidelines for Fuels and Lubes Purchasing*

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'.

List of lubricating oils

The circulating oil (lubricating and cooling oil) must be of the rust and oxidation inhibited type of oil of SAE 30 viscosity grade.

In short, MAN Diesel and Turbo recommends the use of system oils with the following main properties:

- SAE 30 viscosity grade
- BN level 5-10
- adequately corrosion and oxidation inhibited
- adequate detergency and dispersancy.

The adequate dispersion and detergent properties are in order to keep the crankcase and piston cooling spaces clean of deposits.

Alkaline circulating oils are generally superior in this respect.

The major international system oil brands listed below have been tested in service with acceptable results. Some of the oils have also given satisfactory service results during long-term operation on MAN B&W engines running on heavy fuel oil (HFO).

Oils from other companies can be equally suitable. Further information can be obtained from the engine builder or MAN Diesel & Turbo, Copenhagen.
Components for Lubricating Oil System

Lubricating oil pump

The lubricating oil pump can be of the displacement wheel, or the centrifugal type:

Lubricating oil viscosity, specified...75 cSt at 50 °C
Lubricating oil viscosity............ maximum 400 cSt *
Lubricating oil flow............... see ‘List of capacities’
Design pump head.........................4.0 bar
Delivery pressure .........................4.0 bar
Max. working temperature..............70 °C

* 400 cSt is specified, as it is normal practice when starting on cold oil, to partly open the bypass valves of the lubricating oil pumps, so as to reduce the electric power requirements for the pumps.

The flow capacity must be within a range from 100 to 112% of the capacity stated.

The pump head is based on a total pressure drop across cooler and filter of maximum 1 bar.

Referring to Fig. 8.01.01, the bypass valve shown between the main lubricating oil pumps may be omitted in cases where the pumps have a built-in bypass or if centrifugal pumps are used.

If centrifugal pumps are used, it is recommended to install a throttle valve at position ‘005’ to prevent an excessive oil level in the oil pan if the centrifugal pump is supplying too much oil to the engine.

During trials, the valve should be adjusted by means of a device which permits the valve to be closed only to the extent that the minimum flow area through the valve gives the specified lubricating oil pressure at the inlet to the engine at full normal load conditions. It should be possible to fully open the valve, e.g. when starting the engine with cold oil.

It is recommended to install a 25 mm valve (pos. 006), with a hose connection after the main lubricating oil pumps, for checking the cleanliness of the lubricating oil system during the flushing procedure. The valve is to be located on the underside of a horizontal pipe just after the discharge from the lubricating oil pumps.

Lubricating oil cooler

The lubricating oil cooler must be of the shell and tube type made of seawater resistant material, or a plate type heat exchanger with plate material of titanium, unless freshwater is used in a central cooling water system.

Lubricating oil viscosity, specified...75 cSt at 50 °C
Lubricating oil flow............... see ‘List of capacities’
Heat dissipation .................. see ‘List of capacities’
Lubricating oil temperature, outlet cooler......45 °C
Working pressure on oil side...............4.0 bar
Pressure drop on oil side ............maximum 0.5 bar
Cooling water flow............... see ‘List of capacities’
Cooling water temperature at inlet:
seawater.................................32 °C
freshwater............................36 °C
Pressure drop on water side .......maximum 0.2 bar

The lubricating oil flow capacity must be within a range from 100 to 112% of the capacity stated.

The cooling water flow capacity must be within a range from 100 to 112% of the capacity stated.

To ensure the correct functioning of the lubricating oil cooler, we recommend that the seawater temperature is regulated so that it will not be lower than 10 °C.

The pressure drop may be larger, depending on the actual cooler design.

Lubricating oil temperature control valve

The temperature control system can, by means of a three-way valve unit, by-pass the cooler totally or partly.

Lubricating oil viscosity, specified....75 cSt at 50 °C
Lubricating oil flow............... see ‘List of capacities’
Temperature range, inlet to engine ........40 - 47 °C
Lubricating oil full flow filter

Lubricating oil flow ............................. see ‘List of capacities’
Working pressure........................................... 4.0 bar
Test pressure............................................ according to class rules
Absolute fineness........................................ 40 μm*
Working temperature ............... approximately 45 °C
Oil viscosity at working temp. ............. 90 - 100 cSt
Pressure drop with clean filter .... maximum 0.2 bar
Filter to be cleaned
at a pressure drop................................. maximum 0.5 bar

* The absolute fineness corresponds to a nominal fineness of approximately 25 μm at a retaining rate of 90%.

If a filter with a back-flushing arrangement is installed, the following should be noted:

- The required oil flow, specified in the ‘List of capacities’, should be increased by the amount of oil used for the back-flushing, so that the lubricating oil pressure at the inlet to the main engine can be maintained during cleaning.

- If an automatically cleaned filter is installed, it should be noted that in order to activate the cleaning process, certain makes of filter require a higher oil pressure at the inlet to the filter than the pump pressure specified. Therefore, the pump capacity should be adequate for this purpose, too.

The flow capacity must be within a range from 100 to 112% of the capacity stated.

The full-flow filter should be located as close as possible to the main engine.

If a double filter (duplex) is installed, it should have sufficient capacity to allow the specified full amount of oil to flow through each side of the filter at a given working temperature with a pressure drop across the filter of maximum 0.2 bar (clean filter).
Flushing of lubricating oil components and piping system at the shipyard

During installation of the lubricating oil system for the main engine, it is important to minimise or eliminate foreign particles in the system. This is done as a final step onboard the vessel by flushing the lubricating oil components and piping system of the MAN B&W main engine types MC/MC-C before starting the engine.

At the shipyard, the following main points should be observed during handling and flushing of the lubricating oil components and piping system:

• **Before and during installation**
  Components delivered from subsuppliers, such as pumps, coolers and filters, are expected to be clean and rust protected. However, these must be spot-checked before being connected to the piping system.

  All piping must be ‘finished’ in the workshop before mounting onboard, i.e. all internal welds must be ground and piping must be acid-treated followed by neutralisation, cleaned and corrosion protected.

  Both ends of all pipes must be closed/sealed during transport.

  Before final installation, carefully check the inside of the pipes for rust and other kinds of foreign particles.

  Never leave a pipe end uncovered during assembly.

• **Bunkering and filling the system**
  Tanks must be cleaned manually and inspected before filling with oil.

  When filling the oil system, MAN Diesel & Turbo recommends that new oil is bunkered through 6 μm fine filters, or that a purifier system is used. New oil is normally delivered with a cleanliness level of XX/23/19 according to ISO 4406 and, therefore, requires further cleaning to meet our specification.

• **Flushing the piping with engine bypass**
  When flushing the system, the first step is to bypass the main engine oil system. Through temporary piping and/or hosing, the oil is circulated through the vessel’s system and directly back to the main engine oil sump tank.

![Diagram of lubricating oil system with temporary hosing/piping](image-url)

*Fig. 8.05.01: Lubricating oil system with temporary hosing/piping for flushing at the shipyard*
If the system has been out of operation, unused for a long time, it may be necessary to spot-check for signs of corrosion in the system. Remove end covers, bends, etc., and inspect accordingly.

It is important during flushing to keep the oil warm, approx 60 °C, and the flow of oil as high as possible. For that reason it may be necessary to run two pumps at the same time.

- **Filtering and removing impurities**
  In order to remove dirt and impurities from the oil, it is essential to run the purifier system during the complete flushing period and/or use a bypass unit with a 6 μm fine filter and sump-to-sump filtration, see Fig. 8.05.01.

  Furthermore, it is recommended to reduce the filter mesh size of the main filter unit to 10-25 μm (to be changed again after sea trial). This can lead to a reduction of the flushing time.

  The flushing time depends on the system type, the condition of the piping and the experience of the yard. (15 to 26 hours should be expected).

- **Cleanliness level, measuring kit and flushing log**
  MAN Diesel & Turbo specifies ISO 4406 XX/19/15 as accepted cleanliness level for the MC/MC-C lubricating oil system.

  The amount of contamination contained in system samples can be estimated by means of the Pall Fluid Contamination Comparator combined with the Portable Analysis Kit, HPCA-Kit-0, which is used by MAN Diesel & Turbo. This kit and the Comparator included is supplied by Pall Corporation, USA, www.pall.com

  It is important to record the flushing condition in statements to all inspectors involved. The MAN Diesel & Turbo Flushing Log form, which is available on request, or a similar form is recommended for this purpose.

- **Flushing the engine oil system**
  The second step of flushing the system is to flush the complete engine oil system. The procedure depends on the engine type and the condition in which the engine is delivered from the engine builder. For detailed information we recommend contacting the engine builder or MAN Diesel & Turbo.

- **Inspection and recording in operation**
  Inspect the filters before and after the sea trial.

  During operation of the oil system, check the performance and behaviour of all filters, and note down any abnormal condition. Take immediate action if any abnormal condition is observed. For instance, if high differential pressure occurs at short intervals, or in case of abnormal back flushing, check the filters and take appropriate action.

  Further information and recommendations regarding flushing, the specified cleanliness level and how to measure it, and how to use the NAS 1638 oil cleanliness code as an alternative to ISO 4406, are available from MAN Diesel & Turbo.
Lubricating oil outlet

An example of a lubricating oil outlet to bottom tank is shown in Fig. 8.05.02.

Fig. 8.05.02: Example of a lubricating oil outlet to bottom tank, S46MC-C/ME-B and S42MC is shown
Lubricating Oil Tank

Oil level with Qm3 oil in bottom tank and with pumps stopped

Outlet from engine, 250 mm, having it’s bottom edge below the oil level (to obtain gas seal between crankcase and bottom tank)

Fig. 8.06.01a: Lubricating oil tank, with cofferdam
Note:
When calculating the tank heights, allowance has not been made for the possibility that a quantity of oil in the lubricating oil system outside the engine may be returned to the bottom tank, when the pumps are stopped.

If the system outside the engine is so designed that an amount of the lubricating oil is drained back to the tank, when the pumps are stopped, the height of the bottom tank indicated in Table 8.06.01b has to be increased to include this quantity. If space is limited, however, other solutions are possible.

Crankcase Venting and Bedplate Drain Pipes

Fig. 8.07.01: Crankcase venting

Fig. 8.07.02: Bedplate drain pipes
Engine and Tank Venting to the Outside Air

Venting of engine plant equipment separately

The various tanks, engine crankcases and turbochargers should be provided with sufficient venting to the outside air.

MAN Diesel & Turbo recommends to vent the individual components directly to outside air above deck by separate venting pipes as shown in Fig. 8.07.03a.

It is not recommended to join the individual venting pipes in a common venting chamber as shown in Fig. 8.07.03b.

In order to avoid condensed oil (water) from blocking the venting, all vent pipes must be vertical or laid with an inclination.

Additional information on venting of tanks is available from MAN Diesel & Turbo, Copenhagen.

Fig. 8.07.03a: Separate venting of all systems directly to outside air above deck

Fig. 8.07.03b: Venting through a common venting chamber is not recommended
Cylinder Lubrication
Cylinder Lubricating Oil System

The cost of the cylinder lubricating oil is one of the largest contributions to total operating costs, next to the fuel oil cost. Another aspect is that the lubrication rate has a great influence on the cylinder condition, and thus on the overhauling schedules and maintenance costs.

It is therefore of the utmost importance that the cylinder lubricating oil system as well as its operation is optimised.

Cylinder oils

In short, MAN Diesel and Turbo recommends the use of cylinder oils with the following main properties:

- SAE 50 viscosity grade
- high detergency
- BN 100 for high-sulphur fuel
- BN 40 for low-sulphur fuel.

A BN 100 cylinder oil is to be used as the default choice of oil and it may be used on all fuel types. However, in case of the engine running on fuel with sulphur content lower than 1.5% for more than 2 weeks, we recommend to change to a lower BN cylinder oil such as a BN 40.

Cylinder lubricators and service tank

The cylinder lubricators can be either the electronic MAN B&W Alpha Cylinder Lubricators or a mechanical type driven by the engine. Basic design is MAN B&W Alpha Cylinder Lubricators, EoD: 4 42 104. The options are listed in the Extent of Delivery.

The cylinder lube oil is supplied from a gravity-feed cylinder oil service tank to where it is being pumped from the cylinder oil storage tank. The size of the cylinder oil service tank depends on the owner’s and yard’s requirements, and it is normally dimensioned for minimum two days’ consumption.

The cylinder lubricating oil consumption could be monitored by installing a flow meter on the pressure side of the pump in the supply line to the service tank, if required by the shipowner.

Provided the oil level in the service tank is kept the same every time the flow meter is being read, the accuracy is satisfactory.

Two-tank cylinder oil supply system

A cylinder lubricating oil supply system for engine plants with MAN B&W Alpha Cylinder Lubricators is shown in Fig. 9.02.02 and for plants with mechanical cylinder lubricators in Fig. 9.03.03. In both cases a dual system for supply of two different BN cylinder oils is shown.

Cylinder oil feed rate (dosage)

The recommendations are valid for all plants, whether controllable pitch or fixed pitch propellers are used.

In case of average sulphur content, the average cylinder oil feed rate at all loads for MAN B&W Alpha Cylinder Lubricator is 0.7 g/kWh. Adjustment of the cylinder oil dosage of the MAN B&W Alpha Cylinder Lubricator to the sulphur content in the fuel being burnt is further explained in Section 9.02.

The nominal cylinder oil feed rate at nominal MCR for a mechanical cylinder lubricator is typically 1.0 - 1.5 g/kWh.

Further information about cylinder lubrication on different fuel types is available in our publication:

Operation on Low-Sulphur Fuels

The publication is available at www.marine.man.eu → 'Two-Stroke' → ‘Technical Papers’.
List of cylinder oils

The major international cylinder oil brands listed below have been tested in service with acceptable results. Some of the oils have also given satisfactory service results during long-term operation on MAN B&W engines running on heavy fuel oil (HFO).

Oils from other companies can be equally suitable. Further information can be obtained from the engine builder or MAN Diesel & Turbo, Copenhagen.
MAN B&W Alpha Cylinder Lubrication System

The MAN B&W Alpha cylinder lubrication system, see Figs. 9.02.02 and 9.02.03, is designed to supply cylinder oil intermittently, every 2 to 20 engine revolutions with electronically controlled timing and dosage at a defined position.

Cylinder lubricating oil is fed to the engine by means of a pump station which as standard is mounted on the engine, EoD: 4 42 150, or could be placed in the engine room, option: 4 42 152.

The pump station has two pumps (one operating, the other stand-by with automatic start up) with in-line filters and a heater, see Fig. 9.02.02.

The oil fed to the injectors is pressurised by means of one or two Alpha Lubricators placed on each cylinder and equipped with small multi-piston pumps, see Fig. 9.02.03.

Accumulator tanks on the lubricator inlet pipes ensure adequate filling of the lubricator while accumulators on the outlet pipes serve to dampen the pressure fluctuations. The oil pipes fitted on the engine is shown in Fig. 9.02.03.

On engines with double lubricators, a by-pass valve allows for circulating and heating the cylinder oil before starting the engine under cold engine room conditions. On engines with one lubricator per cylinder, this is done by means of the valve on the cylinderblock intended for emptying the accumulator.

Prior to start-up, the cylinders can be pre-lubricated and, during the running-in period, the operator can choose to increase the lubricating oil feed rate to a max. setting of 200%.

System control units

The cylinder lubrication system is controlled by the Master Control Unit (MCU) which calculates the injection frequency on the basis of the engine-speed signal given by the tacho signal (ZE) and the fuel index.

Lubricating control functions such as 'mep dependent' and 'load change dependent' are all incorporated in the MAN B&W Alpha cylinder lubrication system.

The MAN B&W Alpha Cylinder Lubricator is preferably to be controlled in accordance with the Alpha Adaptive Cylinder oil Control (Alpha ACC) feed rate system. The Alpha ACC is explained in the following page.

The MCU is equipped with a Backup Control Unit (BCU) which, if the MCU malfunctions, activates an alarm and takes control automatically or manually, via a Switch Board Unit (SBU), Fig. 9.02.04.

The MCU, BCU and SBU together comprise the Alpha Cylinder Lubricator Control Unit (ALCU) in shape of a single steel cabinet which is, as standard, located in the Engine Control Room. Fig. 9.02.05 shows the wiring diagram for the MAN B&W Alpha Cylinder Lubrication System.

The yard supply should be according to the items shown in Fig. 9.02.02 within the broken line.
Alpha Adaptive Cylinder Oil Control (Alpha ACC)

It is a well-known fact that the actual need for cylinder oil quantity varies with the operational conditions such as load and fuel oil quality. Consequently, in order to perform the optimal lubrication – cost-effectively as well as technically – the cylinder lubricating oil dosage should follow such operational variations accordingly.

The Alpha lubricating system offers the possibility of saving a considerable amount of cylinder lubricating oil per year and, at the same time, to obtain a safer and more predictable cylinder condition.

Alpha ACC (Adaptive Cylinder-oil Control) is the lubrication mode for MAN B&W two-stroke engines, i.e. lube oil dosing proportional to the engine load and proportional to the sulphur content in the fuel oil being burnt.

Working principle

The feed rate control should be adjusted in relation to the actual fuel quality and amount being burnt at any given time.

The following criteria determine the control:

- The cylinder oil dosage shall be proportional to the sulphur percentage in the fuel
- The cylinder oil dosage shall be proportional to the engine load (i.e. the amount of fuel entering the cylinders)
- The actual feed rate is dependent of the operating pattern and determined based on engine wear and cylinder condition.

The implementation of the above criteria will lead to an optimal cylinder oil dosage.

Specific minimum dosage with Alpha ACC

The recommendations are valid for all plants, whether controllable pitch or fixed pitch propellers are used. The specific minimum dosage at low-sulphur fuels is set at 0.6 g/kWh.

After a running-in period of 500 hours, the feed rate sulphur proportional factor is 0.20 - 0.34 g/kWh × S%. The actual ACC factor will be based on cylinder condition, and preferably a cylinder oil feed rate sweep test should be applied.

Examples of average cylinder oil consumption based on calculations of the average worldwide sulphur content used on MAN B&W two-stroke engines are shown in Fig. 9.02.01a and b.

Working principle

The feed rate control should be adjusted in relation to the actual fuel quality and amount being burnt at any given time.

The following criteria determine the control:

- The cylinder oil dosage shall be proportional to the sulphur percentage in the fuel
- The cylinder oil dosage shall be proportional to the engine load (i.e. the amount of fuel entering the cylinders)
- The actual feed rate is dependent of the operating pattern and determined based on engine wear and cylinder condition.

The implementation of the above criteria will lead to an optimal cylinder oil dosage.

Specific minimum dosage with Alpha ACC

The recommendations are valid for all plants, whether controllable pitch or fixed pitch propellers are used. The specific minimum dosage at low-sulphur fuels is set at 0.6 g/kWh.

After a running-in period of 500 hours, the feed rate sulphur proportional factor is 0.20 - 0.34 g/kWh × S%. The actual ACC factor will be based on cylinder condition, and preferably a cylinder oil feed rate sweep test should be applied.

Examples of average cylinder oil consumption based on calculations of the average worldwide sulphur content used on MAN B&W two-stroke engines are shown in Fig. 9.02.01a and b.

Further information on cylinder oil as a function of fuel oil sulphur content, alkalinity of lubricating oil and operating pattern as well as assessing the engine wear and cylinder condition is available from MAN Diesel & Turbo, Copenhagen.
Pump Station and MAN B&W Alpha Cylinder Lubricators on Engine

The letters refer to list of ‘Counterflanges’
The item No. refer to ‘Guidance values Automation’

Fig. 9.02.03: MAN B&W Alpha cylinder lubricators with piping and instrumentation on engine

#) In case of COLD engine room conditions, open the valve to circulate and heat up the cylinder oil. The valve is then to be closed before starting.
Lubricator Control System

The external electrical system must be capable of providing the MCU and BCU with an un-interruptible supply of 24 Volt DC power.

The MAN B&W Alpha Cylinder Lubricator System is equipped with the following (Normally Closed) alarms:

- MCU fail
- MCU power fail
- MCU common alarm
- BCU in control
- BCU fail
- BCU power fail

and slow down (Normally Open) for:

- Electronic cylinder lubricator system

The system has a connection for coupling it to a computer system or a Display Unit (HMI panel) so that engine speed, fuel index, injection frequency, alarms, etc. can be monitored.

The HMI panel for mounting in Engine Control Room (option: 4 42 660) or on the engine (option: 4 42 160) can be delivered separately.

For the actual number of cylinder lubrication points on the specific engine see Fig. 9.02.03

Fig. 9.02.04: Control of the MAN B&W Alpha Cylinder Lubrication System, one lubricator per cylinder
Fig. 9.02.05: Wiring diagram for MAN B&W Alpha Cylinder Lubrication System, one lubricator per cylinder
Fig. 9.02.05: Suggestion for small heating box with filter
Mechanical Cylinder Lubricators

Mechanical cylinder lubricator(s), can be mounted on the fore end of the engine, the size of which will decide the number of lubricators needed. If driven by the engine in sync with the crankshaft movement, the lubricators could deliver timed injection of the cylinder lubrication oil.

The lubricator(s) should have a built-in capability for adjustment of the oil quantity and be provided with a sight glass for each lubricating point.

The lubricators should be fitted with:
- Electric heating coils
- Low flow and low level alarms.

In the ‘Engine Speed Dependent’ design, the lubricator pumps a fixed amount of oil to the cylinders for each engine revolution. Mainly for plants with controllable pitch propeller, the lubricators could, alternatively, be fitted with a mechanical lubrication system which controls the dosage in proportion to the Mean Effective Pressure (MEP).

An ‘Engine Speed Dependent’ as well as a ‘MEP Dependent’ mechanical lubricator could be equipped with a ‘Load Change Dependent’ system, by which the cylinder feed oil rate is automatically increased during starting, manoeuvring and, preferably, during sudden load changes, see Fig. 9.03.02.

In that case, the signal for the ‘Load Change Dependent’ system comes from the electronic governor.

The letters refer to list of ‘Counterflanges’

Piston Rod Stuffing
Box Drain Oil
Stuffing Box Drain Oil System

For engines running on heavy fuel, it is important that the oil drained from the piston rod stuffing boxes is not led directly into the system oil, as the oil drained from the stuffing box is mixed with sludge from the scavenge air space.

The performance of the piston rod stuffing box on the engines has proved to be very efficient, primarily because the hardened piston rod allows a higher scraper ring pressure.

The amount of drain oil from the stuffing boxes is about 5 - 10 litres/24 hours per cylinder during normal service. In the running-in period, it can be higher.

The relatively small amount of drain oil is led to the general oily waste drain tank, HFO settling tank or is burnt in the incinerator, Fig. 10.01.01. (Yard's supply).

Fig. 10.01.01: Stuffing box drain oil system
Central Cooling Water System
Central Cooling

The water cooling can be arranged in several configurations, the most common system choice being a central cooling water system.

Advantages of the central cooling system:

• Only one heat exchanger cooled by seawater, and thus, only one exchanger to be overhauled
• All other heat exchangers are freshwater cooled and can, therefore, be made of a less expensive material
• Few non-corrosive pipes to be installed
• Reduced maintenance of coolers and components
• Increased heat utilisation.

Disadvantages of the central cooling system:

• Three sets of cooling water pumps (seawater, central water and jacket water.
• Higher first cost.

For information on the alternative Seawater Cooling System, see Chapter 12.

An arrangement common for the main engine and MAN Diesel & Turbo auxiliary engines is available on request.

For further information about common cooling water system for main engines and auxiliary engines please refer to our publication:

*Uni-concept Auxiliary Systems for Two-Stroke Main Engines and Four-Stroke Auxiliary Engines*

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'.

→
Central Cooling Water System

The central cooling water system is characterised by having only one heat exchanger cooled by seawater, and by the other coolers, including the jacket water cooler, being cooled by central cooling water.

In order to prevent too high a scavenge air temperature, the cooling water design temperature in the central cooling water system is normally 36 °C, corresponding to a maximum seawater temperature of 32 °C.

Our recommendation of keeping the cooling water inlet temperature to the main engine scavenge air cooler as low as possible also applies to the central cooling system. This means that the temperature control valve in the central cooling water circuit is to be set to minimum 10 °C, whereby the temperature follows the outboard seawater temperature when central cooling water temperature exceeds 10 °C.

For external pipe connections, we prescribe the following maximum water velocities:

- Jacket water: 3.0 m/s
- Central cooling water: 3.0 m/s
- Seawater: 3.0 m/s

Regardings the lubricating oil coolers, this valve should be adjusted so that the inlet temperature of the cooling water is not below 10 °C.

Air pockets, if any, in the pipe line between the pumps, must be vented to the expansion tank.

The letters refer to list of ‘Counterflanges‘, Fig. 5.10.01
The item No. refer to ‘Guidance values automation‘

Fig. 11.02.01: Central cooling water system
Components for Central Cooling Water System

**Seawater cooling pumps**

The pumps are to be of the centrifugal type.

Seawater flow....................... see ‘List of Capacities’
Pump head.....................................................2.5 bar
Test pressure..........................according to class rules
Working temperature, normal ..............0-32 °C
Working temperature ...................maximum 50 °C

The flow capacity must be within a range from 100 to 110% of the capacity stated.

The differential pressure of the pumps is to be determined on the basis of the total actual pressure drop across the cooling water system.

**Central cooler**

The cooler is to be of the shell and tube or plate heat exchanger type, made of seawater resistant material.

Heat dissipation...................... see ‘List of Capacities’
Central cooling water flow .... see ‘List of Capacities’
Central cooling water temperature, outlet........36 °C
Pressure drop on central cooling side ....max. 0.2 bar
Seawater flow.......................... see ‘List of Capacities’
Seawater temperature, inlet ..............32 °C
Pressure drop on seawater side .............maximum 0.2 bar

The pressure drop may be larger, depending on the actual cooler design.

The heat dissipation and the seawater flow figures are based on MCR output at tropical conditions, i.e. a seawater temperature of 32 °C and an ambient air temperature of 45 °C.

Overload running at tropical conditions will slightly increase the temperature level in the cooling system, and will also slightly influence the engine performance.

**Central cooling water pumps**

The pumps are to be of the centrifugal type.

Central cooling water flow... see ‘List of Capacities’
Pump head.....................................................2.5 bar
Delivery pressure .................depends on location of expansion tank
Test pressure..........................according to class rules
Working temperature ..............80 °C
Design temperature .....................100 °C

The flow capacity must be within a range from 100 to 110% of the capacity stated.

The ‘List of Capacities’ covers the main engine only. The differential pressure provided by the pumps is to be determined on the basis of the total actual pressure drop across the cooling water system.

**Central cooling water thermostatic valve**

The low temperature cooling system is to be equipped with a three-way valve, mounted as a mixing valve, which by-passes all or part of the fresh water around the central cooler.

The sensor is to be located at the outlet pipe from the thermostatic valve and is set so as to keep a temperature level of minimum 10 °C.
Jacket water system

Due to the central cooler the cooling water inlet temperature is about 4 °C higher for this system compared to the seawater cooling system. The input data are therefore different for the scav- enge air cooler, the lube oil cooler and the jacket water cooler.

The heat dissipation and the central cooling water flow figures are based on an MCR output at tropical conditions, i.e. a maximum seawater temperature of 32 °C and an ambient air temperature of 45 °C.

Jacket water cooling pump

The pumps are to be of the centrifugal type.
Jacket water flow ................ see ‘List of Capacities’
Pump head ...................................................3.0 bar
Delivery pressure ...............depends on location of expansion tank
Test pressure.....................according to class rules
Working temperature ..................... 80 °C
Design temperature ......................... 100 °C

The flow capacity must be within a range from 100 to 110% of the capacity stated.

The stated of capacities cover the main engine only. The pump head of the pumps is to be determined on the basis of the total actual pressure drop across the cooling water system.

Scavenge air cooler

The scavenge air cooler is an integrated part of the main engine.

Heat dissipation ....................... see ‘List of Capacities’
Central cooling water flow .......... see ‘List of Capacities’
Central cooling temperature, inlet .......... 36 °C
Pressure drop on FW-LT water side ........ approx. 0.5 bar

Lubricating oil cooler

See Chapter 8 ‘Lubricating Oil’.

Cooling water pipes

Diagrams of cooling water pipes are shown in Figs. 12.03.01.

Jacket water cooler

The cooler is to be of the shell and tube or plate heat exchanger type.

Heat dissipation ....................... see ‘List of Capacities’
Jacket water flow ................ see ‘List of Capacities’
Jacket water temperature, inlet ........... 80 °C
Pressure drop on jacket water side ...... max. 0.2 bar
Central cooling water flow .... see ‘List of Capacities’
Central cooling water temperature, inlet ...... approx. 42 °C
Pressure drop on Central cooling water side ........ max. 0.2 bar

The other data for the jacket cooling water system can be found in Chapter 12.

For further information about a common cooling water system for main engines and MAN Diesel & Turbo auxiliary engines, please refer to our publication:

Uni-concept Auxiliary Systems for Two-Stroke Main Engines and Four-Stroke Auxiliary Engines

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'.
Seawater Systems

The water cooling can be arranged in several configurations, the most simple system choices being seawater and central cooling water system:

- **A seawater cooling system** and a jacket cooling water system

  - The advantages of the seawater cooling system are mainly related to first cost, viz:
    - Only two sets of cooling water pumps (seawater and jacket water)
    - Simple installation with few piping systems.

  Whereas the disadvantages are:

  - Seawater to all coolers and thereby higher maintenance cost
  - Expensive seawater piping of non-corrosive materials such as galvanised steel pipes or Cu-Ni pipes.
Seawater Cooling System

The seawater cooling system is used for cooling, the main engine lubricating oil cooler, the jacket water cooler and the scavenge air cooler, see Fig. 12.02.01.

The lubricating oil cooler for a PTO step-up gear should be connected in parallel with the other coolers. The capacity of the seawater pump is based on the outlet temperature of the seawater being maximum 50 °C after passing through the coolers – with an inlet temperature of maximum 32 °C (tropical conditions), i.e. a maximum temperature increase of 18 °C.

The valves located in the system fitted to adjust the distribution of cooling water flow are to be provided with graduated scales.

The inter-related positioning of the coolers in the system serves to achieve:

- The lowest possible cooling water inlet temperature to the lubricating oil cooler in order to obtain the cheapest cooler. On the other hand, in order to prevent the lubricating oil from stiffening in cold services, the inlet cooling water temperature should not be lower than 10 °C.

- The lowest possible cooling water inlet temperature to the scavenge air cooler, in order to keep the fuel oil consumption as low as possible.

Fig. 12.02.01: Seawater cooling system
Cooling Water Pipes

The letters refer to list of ‘Counterflanges’
The item No. refer to ‘Guidance values automation’

Fig. 12.03.01: Cooling water pipes for engines with one turbocharger
Components for Seawater Cooling System

Seawater cooling pump
The pumps are to be of the centrifugal type.
Seawater flow .................. see ‘List of Capacities’
Pump head ....................... 2.5 bar
Test pressure ................. according to class rule
Working temperature ............ maximum 50 °C

The flow capacity must be within a range from 100 to 110% of the capacity stated.

Lubricating oil cooler
See Chapter 8 ‘Lubricating Oil’.

Scavenge air cooler
The scavenge air cooler is an integrated part of the main engine.
Heat dissipation ............... see ‘List of Capacities’
Seawater flow .................. see ‘List of Capacities’
Seawater temperature, for seawater cooling inlet, max. ................. 32 °C
Pressure drop on cooling water side ........ between 0.1 and 0.5 bar

The heat dissipation and the seawater flow are based on an MCR output at tropical conditions, i.e. seawater temperature of 32 °C and an ambient air temperature of 45 °C.

Jacket water cooler
The cooler is to be of the shell and tube or plate heat exchanger type, made of seawater resistant material.
Heat dissipation ............... see ‘List of Capacities’
Jacket water flow .............. see ‘List of Capacities’
Jacket water temperature, inlet .......... 80 °C
Pressure drop on jacket water side .......... maximum 0.2 bar
Seawater flow .................. see ‘List of Capacities’
Seawater temperature, inlet ................. 38 °C
Pressure drop on seawater side .......... maximum 0.2 bar

The heat dissipation and the seawater flow are based on an MCR output at tropical conditions, i.e. seawater temperature of 32 °C and an ambient air temperature of 45 °C.

Seawater thermostatic valve
The temperature control valve is a three-way valve which can recirculate all or part of the seawater to the pump’s suction side. The sensor is to be located at the seawater inlet to the lubricating oil cooler, and the temperature level must be a minimum of +10 °C.
Seawater flow .................. see ‘List of Capacities’
Temperature range, adjustable within ......................... +5 to +32 °C
Jacket Cooling Water System

The jacket cooling water system is used for cooling the cylinder liners, cylinder covers and exhaust valves of the main engine and heating of the fuel oil drain pipes, see Fig. 12.05.01.

The jacket water pump draws water from the jacket water cooler outlet and delivers it to the engine.

At the inlet to the jacket water cooler there is a thermostatically controlled regulating valve, with a sensor at the engine cooling water outlet, which keeps the main engine cooling water outlet at a temperature of 80 °C.

The engine jacket water must be carefully treated, maintained and monitored so as to avoid corrosion, corrosion fatigue, cavitation and scale formation. It is recommended to install a preheater if preheating is not available from the auxiliary engines jacket cooling water system.

The venting pipe in the expansion tank should end just below the lowest water level, and the expansion tank must be located at least 15 m above the top of the exhaust valve.

The freshwater generator, if installed, may be connected to the seawater system if the generator does not have a separate cooling water pump. The generator must be coupled in and out slowly over a period of at least 3 minutes.

For external pipe connections, we prescribe the following maximum water velocities:

<table>
<thead>
<tr>
<th>Water Type</th>
<th>Maximum Velocity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jacket water</td>
<td>3.0 m/s</td>
</tr>
<tr>

The item No. refer to 'Guidance values automation'

Fig. 12.06.01: Jacket cooling water pipes for engines with MAN Diesel turbochargers, type TCA, and ABB turbochargers, type TPL
Components for Jacket Cooling Water System

Jacket water cooling pump

The pumps are to be of the centrifugal type.

Jacket water flow ............... see ‘List of Capacities'
Pump head..............................................3.0 bar
Delivery pressure ...................... depends on position of expansion tank
Test pressure......................... according to class rule
Working temperature, ............. 80 °C, max. 100 °C

The flow capacity must be within a range from 100 to 110% of the capacity stated.

The stated capacities cover the main engine only. The pump head of the pumps is to be determined based on the total actual pressure drop across the cooling water system.

Freshwater generator

If a generator is installed in the ship for production of freshwater by utilising the heat in the jacket water cooling system it should be noted that the actual available heat in the jacket water system is lower than indicated by the heat dissipation figures given in the ‘List of Capacities’. This is because the latter figures are used for dimensioning the jacket water cooler and hence incorporate a safety margin which can be needed when the engine is operating under conditions such as, e.g. overload. Normally, this margin is 10% at nominal MCR.

The calculation of the heat actually available at specified MCR for a derated diesel engine is stated in Chapter 6 ‘List of Capacities’.

For illustration of installation of fresh water generator see Fig. 12.05.01.

Jacket water thermostatic valve

The temperature control system is equipped with a three-way valve mounted as a diverting valve, which by-pass all or part of the jacket water around the jacket water cooler.

The sensor is to be located at the outlet from the main engine, and the temperature level must be adjustable in the range of 70-90 °C.

Jacket water preheater

When a preheater, see Fig. 12.05.01, is installed in the jacket cooling water system, its water flow, and thus the preheater pump capacity, should be about 10% of the jacket water main pump capacity.

Based on experience, it is recommended that the pressure drop across the preheater should be approx. 0.2 bar. The preheater pump and main pump should be electrically interlocked to avoid the risk of simultaneous operation.

The preheater capacity depends on the required preheating time and the required temperature increase of the engine jacket water. The temperature and time relations are shown in Fig. 12.08.01.

In general, a temperature increase of about 35 °C (from 15 °C to 50 °C) is required, and a preheating time of 12 hours requires a preheater capacity of about 1% of the engine’s nominal MCR power.

Deaerating tank

Design and dimensions of the deaerating tank are shown in Fig. 12.07.01 ‘Deaerating tank’ and the corresponding alarm device is shown in Fig. 12.07.02 ‘Deaerating tank, alarm device’.

Expansion tank

The total expansion tank volume has to be approximate 10% of the total jacket cooling water amount in the system.

Fresh water treatment

MAN Diesel & Turbo’s recommendations for treatment of the jacket water/freshwater are available on request.

Temperature at Start of Engine

In order to protect the engine, some minimum temperature restrictions have to be considered before starting the engine and, in order to avoid corrosive attacks on the cylinder liners during starting.

The temperature and speed/load restrictions vary with type of propeller as explained below.

Fixed pitch propeller plants

- Normal start of engine:

  Normally, a minimum engine jacket water temperature of 50 °C is recommended before the engine may be started and run up gradually from 80% to 90% of specified MCR speed (SMCR rpm) during 30 minutes.

  For running up between 90% and 100% of SMCR rpm, it is recommended that the speed be increased slowly over a period of 60 minutes.

- Start of cold engine:

  In exceptional circumstances where it is not possible to comply with the above-mentioned recommendation, a minimum of 20 °C can be accepted before the engine is started and run up slowly to 80% of SMCR rpm.

  Before exceeding 80% SMCR rpm, a minimum jacket water temperature of 50 °C should be obtained before the above described normal start load-up procedure may be continued.

Controllable pitch propeller plants

- Normal start of engine:

  Normally, a minimum engine jacket water temperature of 50 °C is recommended before the engine may be started and run up gradually from 50% to 75% of specified MCR load (SMCR power) during 30 minutes.

  For running up between 75% and 100% of SMCR power, it is recommended that the load be increased slowly over a period of 60 minutes.

- Start of cold engine:

  In exceptional circumstances where it is not possible to comply with the above-mentioned recommendation, a minimum of 20 °C can be accepted before the engine is started and run up slowly to 50% of SMCR power.

  Before exceeding 50% SMCR power, a minimum jacket water temperature of 50 °C should be obtained before above described normal start load-up procedure may be continued.

Jacket water warming-up time

The time period required for increasing the jacket water temperature from 20 °C to 50 °C will depend on the amount of water in the jacket cooling water system, and the engine load.

Note:

The above considerations for start of cold engine are based on the assumption that the engine has already been well run-in.
Preheating of diesel engine

Preheating during standstill periods

During short stays in port (i.e. less than 4-5 days), it is recommended that the engine is kept pre-heated, the purpose being to prevent temperature variation in the engine structure and corresponding variation in thermal expansions and possible leakages.

The jacket cooling water outlet temperature should be kept as high as possible and should – before starting up – be increased to at least 50 °C, either by means of cooling water from the auxiliary engines, or by means of a built-in preheater in the jacket cooling water system, or a combination.

Fig. 12.08.01: Jacket water preheater, example
Starting and Control Air
Starting and Control Air Systems

The starting air of 30 bar is supplied by the starting air compressors to the starting air receivers and from these to the main engine inlet ‘A’.

Through a reduction station, filtered compressed air at 7 bar is supplied to the engine as:

- Control air for manoeuvring system and for exhaust valve air springs, through engine inlet ‘B’
- Safety air for emergency stop, through inlet ‘C’.

Through a reduction valve, compressed air is supplied at 10 bar to ‘AP’ for turbocharger cleaning (soft blast), and a minor volume used for the fuel valve testing unit.

Please note that the air consumption for control air, safety air, turbocharger cleaning and for fuel valve testing unit are momentary requirements of the consumers.

The components of the starting and control air systems are further described in Section 13.02.

For information about a common starting air system for main engines and MAN Diesel auxiliary engines, please refer to our publication:

*Uni-concept Auxiliary Systems for Two-Stroke Main Engines and Four-Stroke Auxiliary Engines*

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'.

The letters refer to list of ‘Counterflanges’

*) Pipe a nominal dimension: DN100 mm

Fig. 13.01.01: Starting and control air systems
Components for Starting Air System

Starting air compressors

The starting air compressors are to be of the water-cooled, two-stage type with intercooling.

More than two compressors may be installed to supply the total capacity stated.

Air intake quantity:
Reversible engine,
for 12 starts ....................... see ‘List of capacities’
Non-reversible engine,
for 6 starts ......................... see ‘List of capacities’
Delivery pressure ..................... 30 bar

Starting air receivers

The starting air receivers shall be provided with man holes and flanges for pipe connections.

The volume of the two receivers is:
Reversible engine,
for 12 starts ..................... see ‘List of capacities’ *
Non-reversible engine,
for 6 starts ....................... see ‘List of capacities’ *
Working pressure ..................... 30 bar
Test pressure ...................... according to class rule

* The volume stated is at 25 °C and 1,000 mbar

Reduction station for control and safety air

In normal operating, each of the two lines supplies one engine inlet. During maintenance, three isolating valves in the reduction station allow one of the two lines to be shut down while the other line supplies both engine inlets, see Fig. 13.01.01.

Reduction ....................... from 30-10 bar to 7 bar
(Tolerance ±10%)

Flow rate, free air ............ 1,400 Normal liters/min
equal to 0.023 m³/s
Filter, fineness ..................... 40 μm

Reduction valve for turbocharger cleaning etc

Reduction ....................... from 30-10 bar to 7 bar
(Tolerance ±10%)

Flow rate, free air ............ 2,600 Normal liters/min
equal to 0.043 m³/s

The consumption of compressed air for control air, exhaust valve air springs and safety air as well as air for turbocharger cleaning and fuel valve testing is covered by the capacities stated for air receivers and compressors in the list of capacities.

Starting and control air pipes

The piping delivered with and fitted onto the main engine is shown in the following figures in Section 13.03:

Fig. 13.03.01 Starting air pipes
Fig. 13.03.02 Air spring pipes, exhaust valves

Turning gear

The turning wheel has cylindrical teeth and is fitted to the thrust shaft. The turning wheel is driven by a pinion on the terminal shaft of the turning gear, which is mounted on the bedplate.

Engagement and disengagement of the turning gear is effected by displacing the pinion and terminal shaft axially. To prevent the main engine from starting when the turning gear is engaged, the turning gear is equipped with a safety arrangement which interlocks with the starting air system.

The turning gear is driven by an electric motor with a built-in gear and brake. Key specifications of the electric motor and brake are stated in Section 13.04.
Starting and Control Air Pipes

The starting air pipes, Fig. 13.03.01a and b, contain a main starting valve (a ball valve with actuator), a non-return valve, starting air distributor and starting valves.

The main starting valve is combined with the manoeuvring system, which controls the start of the engine. Slow turning before start of engine is an option: 4 50 140 and is recommended by MAN Diesel, see Section 16.01.

The starting air distributor regulates the supply of control air to the starting valves in accordance with the correct firing sequence.

Please note that the air consumption for control air, turbocharger cleaning and for fuel valve testing unit are momentary requirements of the consumers.

For information about a common starting air system for main engines and auxiliary engines, please refer to our publication:

*Uni-concept Auxiliary Systems for Two-Stroke Main Engines and Four-Stroke Auxiliary Engines*

Scavenge Air
Scavenge Air System

Scavenge air is supplied to the engine by one turbocharger located on either the aft end of the engine, option: 4 59 121, or on the exhaust side, option: 4 59 123.

The compressor of the turbocharger draws air from the engine room, through an air filter, and the compressed air is cooled by the scavenge air cooler. The scavenge air cooler is provided with a water mist catcher, which prevents condensed water from being carried with the air into the scavenge air receiver and to the combustion chamber.

The scavenge air system (see Figs. 14.01.01 and 14.02.01) is an integrated part of the main engine.

The engine power figures and the data in the list of capacities are based on MCR at tropical conditions, i.e. a seawater temperature of 32 °C, or freshwater temperature of 36 °C, and an ambient air inlet temperature of 45 °C.

Fig. 14.01.01: Scavenge Air System
Auxiliary Blowers

The engine is provided with a minimum of two electrically driven auxiliary blowers, the actual number depending on the number of cylinders as well as the turbocharger make and amount. Between the scavenge air cooler and the scavenge air receiver, non-return valves are fitted which close automatically when the auxiliary blowers start supplying the scavenge air.

The auxiliary blowers start operating consecutively before the engine is started and will ensure complete scavenging of the cylinders in the starting phase, thus providing the best conditions for a safe start.

During operation of the engine, the auxiliary blowers will start automatically whenever the blower inlet pressure drops below a preset pressure, corresponding to an engine load of approximately 25-35%. The blowers will continue to operate until the blower inlet pressure again exceeds the preset pressure plus an appropriate hysteresis (i.e. taking recent pressure history into account), corresponding to an engine load of approximately 30-40%.

Emergency running

If one of the auxiliary blowers is out of function, the other auxiliary blower will function in the system, without any manual adjustment of the valves being necessary.

Scavenge air cooler requirements

The data for the scavenge air cooler is specified in the description of the cooling water system chosen.

For further information, please refer to our publication titled:

*Influence of Ambient Temperature Conditions*

The publication is available at www.marine.man.eu → 'Two-Stroke' → 'Technical Papers'.

---

**Fig. 14.02.01: Auxiliary blowers for scavenge air system**

---
Control of the Auxiliary Blowers

The auxiliary blowers are fitted onto the main engine and controlled by a system comprising:

1 pc Control Panel
1 pc Starter Panel per Auxiliary Blower
2 pc Pressure Switches

Referring to the diagram of the auxiliary blower control system, Fig. 14.02.02:

- The Control Panel controls the run/stop signals to all Auxiliary Blower Starter Panels. The Control Panel consists of an operation panel and a terminal row interconnected by a 1,200 mm long wire harness.

- The Auxiliary Blower Starter Panels control and protect the Auxiliary Blower motors, one panel with starter per blower.

- The pressure switch ‘P’ controls the run/stop signals, while pressure switch ‘B’ is part of the auxiliary blower alarm circuit.

The control panel is yard’s supply. It can be ordered as an option: 4 55 650.

The starter panels with starters for the auxiliary blower motors are not included, they can be ordered as an option: 4 55 653. (The starter panel design and function is according to MAN Diesel’s diagram, however, the physical layout and choice of components has to be decided by the manufacturer).

Heaters for the blower motors are available as an option: 4 55 155.

---

**Fig. 14.02.02: Diagram of auxiliary blower control system**
Operation Panel for the Auxiliary Blowers

On the operation panel, three control modes are available to run/stop the blowers:

• AUTO – Run/stop is automatically controlled by scavenging air pressure
• MANUAL – Start of all blowers in sequence at intervals of 6 sec
• OFF – The auxiliary blowers are stopped after a set period of time, 30 sec for instance.

The operation panel and terminal row have to be mounted in the Engine Control Room Manoeuvring Console, see Section 16.01.

The control panel for the auxiliary blowers including the operation panel, wiring harness and terminal row is shown in Fig. 14.02.03.

Fig. 14.02.03: Control panel including operation panel, wiring harness and terminal row, option: 4 55 650
Scavenge Air Pipes

Fig. 14.03.02: Scavenge air space, drain pipes
Electric Motor for Auxiliary Blower

The number of auxiliary blowers in a propulsion plant may vary depending on the actual amount of turbochargers as well as space requirements.

**Motor start method and size**

Direct Online Start (DOL) is required for all auxiliary blower electric motors to ensure proper operation under all conditions.

For typical engine configurations, the installed size of the electric motors for auxiliary blowers are listed in Table 14.04.01.

**Special operating conditions**

For engines with Dynamic Positioning (DP) mode in manoeuvring system, option: 4 06 111, larger electric motors are required. This is in order to avoid start and stop of the blowers inside the load range specified for dynamic positioning. The actual load range is to be decided between the owner and the yard.

Engine plants with waste heat recovery exhaust gas bypass and engines with low- and part-load exhaust gas bypass may require less blower capacity, please contact MAN Diesel & Turbo, Copenhagen.

The installed power of the electric motors are based on a voltage supply of 3x440V at 60Hz.

The electric motors are delivered with and fitted onto the engine.

*Table 14.04.01: Electric motor for auxiliary blower, engine with turbocharger located on aft end or exhaust side*
Scavenge Air Cooler Cleaning System

The air side of the scavenge air cooler can be cleaned by injecting a grease dissolving media through 'AK' to a spray pipe arrangement fitted to the air chamber above the air cooler element.

The system is equipped with a drain box with a level switch, indicating any excessive water level.

The piping delivered with and fitted on the engine is shown in Fig 14.05.01.

Drain from water mist catcher

Sludge is drained through ‘AL’ to the drain water collecting tank and the polluted grease dissolvent returns from ‘AM’, through a filter, to the chemical cleaning tank. The cleaning must be carried out while the engine is at standstill.

The ‘AL’ drain line is, during running, used as a permanent drain from the air cooler water mist catcher. The water is led through an orifice to prevent major losses of scavenge air.

Auto Pump Overboard System

It is common practice on board to lead drain water directly overboard via a collecting tank. Before pumping the drain water overboard, it is recommended to measure the oil content. If above 15ppm, the drain water should be lead to the clean bilge tank / bilge holding tank.

If required by the owner, a system for automatic disposal of drain water with oil content monitoring could be built as outlined in Fig. 14.05.02.

The letters refer to list of ‘Counterflanges’

MAN Diesel
Scavenge Air Box Drain System

The scavenge air box is continuously drained through ‘AV’ to a small pressurised drain tank, from where the sludge is led to the sludge tank. Steam can be applied through ‘BV’, if required, to facilitate the draining. See Fig. 14.06.01.

The continuous drain from the scavenge air box must not be directly connected to the sludge tank owing to the scavenge air pressure.

The pressurised drain tank must be designed to withstand full scavenge air pressure and, if steam is applied, to withstand the steam pressure available.

The system delivered with and fitted on the engine is shown in Fig. 14.03.02 Scavenge air space, drain pipes.

Fire in the scavenge air space can be extinguished by steam, this being the basic solution, or, optionally, by water mist or CO₂.

The external system, pipe and flange connections are shown in Fig. 14.07.01 and the piping fitted onto the engine in Fig. 14.07.02.

In the Extent of Delivery, the fire extinguishing system for scavenge air space is selected by the fire extinguishing agent:

- basic solution: 4 55 140 Steam
- option: 4 55 142 Water mist
- option: 4 55 143 CO₂

The key specifications of the fire extinguishing agents are:

**Steam fire extinguishing for scavenge air space**
- Steam pressure: 3-10 bar
- Steam quantity, approx.: 1.9 kg/cyl.

**Water mist fire extinguishing for scavenge air space**
- Freshwater pressure: min. 3.5 bar
- Freshwater quantity, approx.: 1.5 kg/cyl.

**CO₂ fire extinguishing for scavenge air space**
- CO₂ test pressure: 150 bar
- CO₂ quantity, approx.: 3.7 kg/cyl.

The letters refer to list of 'Counterflanges'

Exhaust Gas
Exhaust Gas System

The exhaust gas is led from the cylinders to the exhaust gas receiver where the fluctuating pressures from the cylinders are equalised and from where the gas is led further on to the turbocharger at a constant pressure. See fig. 15.01.01.

Compensators are fitted between the exhaust valve housings and the exhaust gas receiver and between the receiver and the turbocharger. A protective grating is placed between the exhaust gas receiver and the turbocharger. The turbocharger is fitted with a pick-up for monitoring and remote indication of the turbocharger speed.

The exhaust gas receiver and the exhaust pipes are provided with insulation, covered by steel plating.

Turbocharger arrangement and cleaning systems

The turbocharger can either be located on the aft end of the engine, option: 4 59 121, or on the exhaust side of the engine, option: 4 59 123.

The engine is designed for the installation of the MAN turbocharger type TCA, option: 4 59 101, ABB turbocharger type A100, option: 4 59 102, or MHI turbocharger type MET, option: 4 59 103.

All makes of turbochargers are fitted with an arrangement for soft blast cleaning of the turbine side, and optionally water washing of the compressor side, option: 4 59 145, see Figs. 15.02.02 and 15.02.03. Washing of the turbine side is only applicable by special request to TC manufacturer on MAN turbochargers.

Exhaust Gas System for Main Engine

At the specified MCR of the engine, the total back-pressure in the exhaust gas system after the turbocharger (as indicated by the static pressure measured in the piping after the turbocharger) must not exceed 350 mm WC (0.035 bar).

In order to have a back-pressure margin for the final system, it is recommended at the design stage to initially use a value of about 300 mm WC (0.030 bar).

The actual back-pressure in the exhaust gas system at specified MCR depends on the gas velocity, i.e. it is proportional to the square of the exhaust gas velocity, and hence inversely proportional to the pipe diameter to the 4th power. It has by now become normal practice in order to avoid too much pressure loss in the pipings to have an exhaust gas velocity at specified MCR of about 35 m/sec, but not higher than 50 m/sec.

For dimensioning of the external exhaust pipe connections, see the exhaust pipe diameters for 35 m/sec, 40 m/sec, 45 m/sec and 50 m/sec respectively, shown in Table 15.07.02.

As long as the total back-pressure of the exhaust gas system (incorporating all resistance losses from pipes and components) complies with the above-mentioned requirements, the pressure losses across each component may be chosen independently, see proposed measuring points (M) in Fig. 15.05.01. The general design guidelines for each component, described below, can be used for guidance purposes at the initial project stage.

Exhaust gas piping system for main engine

The exhaust gas piping system conveys the gas from the outlet of the turbocharger(s) to the atmosphere.

The exhaust piping is shown schematically in Fig. 15.04.01.

The exhaust system for the main engine comprises:

- Exhaust gas pipes
- Exhaust gas boiler
- Silencer
- Spark arrester (if needed)
- Expansion joints (compensators)
- Pipe bracings.

In connection with dimensioning the exhaust gas piping system, the following parameters must be observed:

- Exhaust gas flow rate
- Exhaust gas temperature at turbocharger outlet
- Maximum pressure drop through exhaust gas system
- Maximum noise level at gas outlet to atmosphere
- Maximum force from exhaust piping on turbocharger(s)
- Sufficient axial and lateral elongation ability of expansion joints
- Utilisation of the heat energy of the exhaust gas.

Items that are to be calculated or read from tables are:

- Exhaust gas mass flow rate, temperature and maximum back pressure at turbocharger gas outlet
- Diameter of exhaust gas pipes
- Utilisation of the exhaust gas energy
- Attenuation of noise from the exhaust pipe outlet
- Pressure drop across the exhaust gas system
- Expansion joints.
Components of the Exhaust Gas System

Exhaust gas boiler

Engine plants are usually designed for utilisation of the heat energy of the exhaust gas for steam production or for heating the thermal oil system. The exhaust gas passes an exhaust gas boiler which is usually placed near the engine top or in the funnel.

It should be noted that the exhaust gas temperature and flow rate are influenced by the ambient conditions, for which reason this should be considered when the exhaust gas boiler is planned. At specified MCR, the maximum recommended pressure loss across the exhaust gas boiler is normally 150 mm WC.

This pressure loss depends on the pressure losses in the rest of the system as mentioned above. Therefore, if an exhaust gas silencer/spark arrester is not installed, the acceptable pressure loss across the boiler may be somewhat higher than the max. of 150 mm WC, whereas, if an exhaust gas silencer/spark arrester is installed, it may be necessary to reduce the maximum pressure loss.

The above mentioned pressure loss across the exhaust gas boiler must include the pressure losses from the inlet and outlet transition pieces.

Exhaust gas compensator after turbocharger

When dimensioning the compensator, option: 4 60 610, for the expansion joint on the turbocharger gas outlet transition piece, option: 4 60 601, the exhaust gas piece and components, are to be so arranged that the thermal expansions are absorbed by expansion joints. The heat expansion of the pipes and the components is to be calculated based on a temperature increase from 20 °C to 250 °C. The max. expected vertical, transversal and longitudinal heat expansion of the engine measured at the top of the exhaust gas transition piece of the turbocharger outlet are indicated in Fig. 15.06.01 and Table 15.06.02 as DA, DB and DC.

The movements stated are related to the engine seating, for DC, however, to the engine centre. The figures indicate the axial and the lateral movements related to the orientation of the expansion joints.

The expansion joints are to be chosen with an elasticity that limits the forces and the moments of the exhaust gas outlet flange of the turbocharger as stated for each of the turbocharger makers in Table 15.06.04. The orientation of the maximum permissible forces and moments on the gas outlet flange of the turbocharger is shown in Fig. 15.06.03.

The above mentioned pressure loss across the exhaust gas boiler must include the pressure losses from the inlet and outlet transition pieces.
Exhaust gas silencer

The typical octave band sound pressure levels from the diesel engine's exhaust gas system – at a distance of one meter from the top of the exhaust gas uptake – are shown in Fig. 15.04.02.

The need for an exhaust gas silencer can be decided based on the requirement of a maximum permissible noise level at a specific position.

The exhaust gas noise data is valid for an exhaust gas system without boiler and silencer, etc.

The noise level is at nominal MCR at a distance of one metre from the exhaust gas pipe outlet edge at an angle of 30° to the gas flow direction.

For each doubling of the distance, the noise level will be reduced by about 6 dB (far-field law).

When the noise level at the exhaust gas outlet to the atmosphere needs to be silenced, a silencer can be placed in the exhaust gas piping system after the exhaust gas boiler.

The exhaust gas silencer is usually of the absorption type and is dimensioned for a gas velocity of approximately 35 m/s through the central tube of the silencer.

An exhaust gas silencer can be designed based on the required damping of noise from the exhaust gas given on the graph.

In the event that an exhaust gas silencer is required – this depends on the actual noise level requirement on the bridge wing, which is normally maximum 60-70 dB(A) – a simple flow silencer of the absorption type is recommended. Depending on the manufacturer, this type of silencer normally has a pressure loss of around 20 mm WC at specified MCR.

Fig. 15.04.02: ISO's NR curves and typical sound pressure levels from the engine's exhaust gas system. The noise levels at nominal MCR and a distance of 1 metre from the edge of the exhaust gas pipe opening at an angle of 30 degrees to the gas flow and valid for an exhaust gas system – without boiler and silencer, etc. Data for a specific engine and cylinder no. is available on request.

Spark arrester

To prevent sparks from the exhaust gas being spread over deck houses, a spark arrester can be fitted as the last component in the exhaust gas system.

It should be noted that a spark arrester contributes with a considerable pressure drop, which is often a disadvantage.

It is recommended that the combined pressure loss across the silencer and/or spark arrester should not be allowed to exceed 100 mm WC at specified MCR. This depends, of course, on the pressure loss in the remaining part of the system, thus if no exhaust gas boiler is installed, 200 mm WC might be allowed.
Calculation of Exhaust Gas Back-Pressure

The exhaust gas back pressure after the turbocharger(s) depends on the total pressure drop in the exhaust gas piping system.

The components, exhaust gas boiler, silencer, and spark arrester, if fitted, usually contribute with a major part of the dynamic pressure drop through the entire exhaust gas piping system.

The components mentioned are to be specified so that the sum of the dynamic pressure drop through the different components should, if possible, approach 200 mm WC at an exhaust gas flow volume corresponding to the specified MCR at tropical ambient conditions. Then there will be a pressure drop of 100 mm WC for distribution among the remaining piping system.

Fig. 15.05.01 shows some guidelines regarding resistance coefficients and back-pressure loss calculations which can be used, if the maker’s data for back-pressure is not available at an early stage of the project.

The pressure loss calculations have to be based on the actual exhaust gas amount and temperature valid for specified MCR. Some general formulas and definitions are given in the following.

Exhaust gas data

M: exhaust gas amount at specified MCR in kg/sec.
T: exhaust gas temperature at specified MCR in °C

Please note that the actual exhaust gas temperature is different before and after the boiler. The exhaust gas data valid after the turbocharger may be found in Chapter 6.

Mass density of exhaust gas (ρ)

\[ ρ \approx 1.293 \times \frac{273}{273 + T} \times 1.015 \text{ in kg/m}^3 \]

The factor 1.015 refers to the average back-pressure of 150 mm WC (0.015 bar) in the exhaust gas system.

Exhaust gas velocity (v)

In a pipe with diameter D the exhaust gas velocity is:

\[ v = \frac{M}{\rho} \times \frac{4}{\pi \times D^2} \text{ in m/s} \]

Pressure losses in pipes (Δp)

For a pipe element, like a bend etc., with the resistance coefficient ζ, the corresponding pressure loss is:

\[ Δp = ζ \times \frac{1}{2} \rho \times v^2 \times \frac{1}{9.81} \text{ in mm WC} \]

where the expression after ζ is the dynamic pressure of the flow in the pipe.

The friction losses in the straight pipes may, as a guidance, be estimated as:

1 mm WC per 1 diameter length

whereas the positive influence of the up-draught in the vertical pipe is normally negligible.

Pressure losses across components (Δp)

The pressure loss Δp across silencer, exhaust gas boiler, spark arrester, rain water trap, etc., to be measured/stated as shown in Fig. 15.05.01 (at specified MCR) is normally given by the relevant manufacturer.

Total back-pressure (ΔpM)

The total back-pressure, measured/stated as the static pressure in the pipe after the turbocharger, is then:

\[ Δp_M = Σ Δp \]

where Δp incorporates all pipe elements and components etc. as described:

Δp_M has to be lower than 350 mm WC.

(At design stage it is recommended to use max. 300 mm WC in order to have some margin for fouling).
Measuring Back Pressure

At any given position in the exhaust gas system, the total pressure of the flow can be divided into dynamic pressure (referring to the gas velocity) and static pressure (referring to the wall pressure, where the gas velocity is zero).

At a given total pressure of the gas flow, the combination of dynamic and static pressure may change, depending on the actual gas velocity. The measurements, in principle, give an indication of the wall pressure, i.e., the static pressure of the gas flow.

It is, therefore, very important that the back pressure measuring points are located on a straight part of the exhaust gas pipe, and at some distance from an 'obstruction', i.e. at a point where the gas flow, and thereby also the static pressure, is stable. Taking measurements, for example, in a transition piece, may lead to an unreliable measurement of the static pressure.

In consideration of the above, therefore, the total back pressure of the system has to be measured after the turbocharger in the circular pipe and not in the transition piece. The same considerations apply to the measuring points before and after the exhaust gas boiler, etc.
Pressure losses and coefficients of resistance in exhaust pipes

Change-over valves

Change-over valve of type with constant cross section

\[ \zeta_a = 0.6 \text{ to } 1.2 \]
\[ \zeta_b = 1.0 \text{ to } 1.5 \]
\[ \zeta_c = 1.5 \text{ to } 2.0 \]

Change-over valve of type with volume

\[ \zeta_a = \zeta_b = \text{about } 2.0 \]

\[ \zeta = 0.05 \]

\[ \zeta = 0.11 \]

\[ \zeta = 0.12 \]

\[ \zeta = 0.16 \]

\[ \zeta = 0.20 \]

\[ \zeta = 0.28 \]

Outlet from top of exhaust gas uptake

\[ \zeta = -1.00 \]

Inlet (from turbocharger)

Fig. 15.07.01a: Exhaust pipe system, with turbocharger located on exhaust side of engine, option: 4 59 123

Fig. 15.07.01b: Exhaust pipe system, with single turbocharger located on aft end of engine, option: 4 59 121
Engine Control System
Engine Control System

The engine is provided with a pneumatic/electric manoeuvring and fuel oil regulating system, which transmits orders from the separate manoeuvring consoles to the engine.

By means of the regulating system it is possible to start, stop, reverse the engine and control the engine speed. The speed setting device on the manoeuvring consoles gives a speed setting signal to the governor, dependent on the desired number of rpm.

At shut-down, the fuel injection is stopped by activating the puncture valves in the fuel pumps, independent of the speed position of the speed setting device.

The layout of the Engine Control System is shown in Fig. 16.01.01 and a diagram of the pneumatic manoeuvring system in Fig. 16.01.02.

Manoeuvring Consoles

The Engine Control System for the MC / MC-C engine is prepared for conventional remote control, having an interface to the Bridge Control (BC) system and the Engine Side Console (ESC).

The main Engine Control Room (ECR) manoeuvring console is to be located in the engine control room. The console with buttons, lamps, etc. recommended by MAN Diesel is shown in Fig. 16.01.07. Components for remote control for a typical installation with bridge control is shown in Fig. 16.01.05.

The layout of the Engine Side Console and instrument panel is shown in Fig. 16.01.06a, b and c. The console and an electronic speed setting device, the governor, are located on the manoeuvring side of the engine.

In the event of breakdown of the normal pneumatic/electric manoeuvring system, the engine can be operated from the Engine Side Console.

![Diagram of Engine Control System Layout](image-url)
Diagram of Manoeuvring System

Fig. 16.01.02b: Diagram of manoeuvring system for reversible engine with FPP and slow turning, no VIT
**Manoeuvring System on Engine**

The basic manoeuvring diagram is applicable for reversible engines, i.e. those with Fixed Pitch Propeller (FPP), and shown in Fig. 16.01.02.

The lever on the Engine Side Console can be set to either Manual or Remote position, see Fig. 16.01.06a, b and c.

In the Manual position the engine is controlled from the Engine Side Console by the push buttons START, STOP, and the AHEAD/ASTERN. The speed is set by the ‘Manual speed setting’ by the handwheel.

In the ‘Remote’ position all signals to the engine are electronic, the START, STOP, AHEAD and ASTERN signals activate the solenoid valves ZV 1137 C, ZV 1136 C, ZV 1141 C and ZV 1142 C respectively, shown in Figs. 16.01.02 and 16.01.05, and the speed setting signal via the electronic governor and the actuator E 1182 C.

The electrical signal comes from the remote control system, i.e. the Bridge Control (BC) console, or from the Engine Control Room (ECR) console.

**Shut down system**

The engine is stopped by activating the puncture valve located in the fuel pump either at normal stopping or at shut down by activating solenoid valve ZV 1103 C, see Fig. 16.01.02.

**Slow turning**

The standard manoeuvring system does not feature slow turning before starting, but for Unattended Machinery Spaces (UMS) we strongly recommend the addition of the slow turning device shown in Fig. 16.01.02 as well as Fig. 16.01.03, option: 4 50 140.

The slow turning valve diverts the starting air to partially bypass the main starting valve. During slow turning the engine will rotate so slowly that, in the event that liquids have accumulated on the piston top, the engine will stop before any harm occurs.

**Control System for Plants with CPP**

Where a controllable pitch propeller is installed, the control system is to be designed in such a way that the operational requirements for the whole plant are fulfilled.

Special attention should be paid to the actual operation mode, e.g. combinator curve with/without constant frequency shaft generator or constant engine speed with a power take off.

The following requirements have to be fulfilled:

- The control system is to be equipped with a load control function limiting the maximum torque (fuel pump index) in relation to the engine speed, in order to prevent the engine from being loaded beyond the limits of the load diagram
- The control system must ensure that the engine load does not increase at a quicker rate than permitted by the scavenge air pressure
- Load changes have to take place in such a way that the governor can keep the engine speed within the required range.

Please contact the engine builder to get specific data.
Sequence Diagram

MAN Diesel's requirements for the control system are indicated graphically in Fig. 16.01.08a, 'Sequence diagram'.

The diagram shows the functions as well as the delays which must be considered in respect to starting 'Ahead' and starting 'A stern', as well as for the activation of the slow down and shut down functions.

On the right of the diagram, a situation is shown where the order 'A stern' is over-ridden by an 'Ahead' order – the engine immediately starts 'Ahead' if the engine speed is above the specified starting level.
Starting Air System

Additional components for slow turning are the slow turning valve in bypass and position nos. 28 and 78
The item No. refers to ‘Guidance values ‘automation’
The letter refers to list of ‘Counterflanges’
The piping is delivered with and fitted onto the engine

Governor Parts and Mode of Operation

The engine is, as standard, provided with an electronic/mechanical type of fuel pump actuator of a make approved by MAN Diesel & Turbo.

The speed setting of the actuator is determined by an electronic signal from the electronic governor of a make approved by MAN Diesel & Turbo. The actuator shaft is connected to the fuel regulating shaft by means of a mechanical linkage.

When selecting the governor, the complexity of the installation has to be considered. We normally distinguish between ‘conventional’ and ‘advanced’ marine installations.

The governor consists of the following elements:

- Actuator
- Revolution transmitter (pick-ups)
- Electronic governor panel
- Power supply unit
- Pressure transmitter for scavenge air.

The actuator, revolution transmitter and the pressure transmitter are mounted on the engine.

The electronic governors must be tailor-made, and the specific layout of the system must be mutually agreed upon by the customer, the governor supplier and the engine builder.

It should be noted that the shut down system, the governor and the remote control system must be compatible if an integrated solution is to be obtained.

The minimum speed is 20-25% of the engines nominal speed when an electronic governor is applied.

Governor for ‘Conventional’ plants

A typical example of a ‘conventional’ marine installation is:

- An engine directly coupled to a fixed pitch propeller.

With a view to such an installation, the engine is, as standard, equipped with a ‘conventional’ electronic governor with actuator of a make approved by MAN Diesel & Turbo, e.g.:

4 65 172 Lyngsø Marine
4 65 174 Kongsberg Maritime
4 65 175 Nabtesco
4 65 176 Mitsui Zosen Systems Research.

As an option on engines without Power Take Off (PTO), a mechanical-hydraulic type of governor is available:

4 65 171 Woodward.

Governor for ‘Advanced’ plants

For more ‘advanced’ marine installations, such as, for example:

- Plants with flexible coupling in the shafting system
- Geared installations
- Plants with disengageable clutch for disconnecting the propeller
- Plants with shaft generator with great requirement for frequency accuracy.
Governor and Remote Control Components

Engine Side Control Console and Instrument Panel

Components included for:

Fixed pitch propeller:
- Remote control – manual engine side control
- Ahead – Astern handle
- Start button
- Stop button

The instrument panel includes:

For reversible engine:
- Tachometer for engine
- Indication for engine side control
- Indication for control room control (remote)
- Indication for bridge control (remote)
- Indication for ‘Ahead’
- Indication for ‘Astern’
- Indication for auxiliary blower running
- Indication and buzzer for wrong way alarm
- Indication for turning gear engaged
- Indication for ‘Shut down’
- Push button for canceling ‘Shut down’, with indication

Fig. 16.01.06c: Engine Side Control console and instrument panel
Engine Control Room Console

1 Free space for mounting of safety panel
2 Tachometer(s) for turbocharger(s)
3 Indication lamps for:
   - Ahead
   - Astern
   - Engine Side Control
   - Control Room Control
   - Wrong way alarm
   - Turning gear engaged
   - Main starting valve in service
   - Main starting valve in blocked mode
   - Remote control
   - Shut down
   - Lamp test

4 Tachometer for main engine
5 Revolution counter
6 Switch and lamps for auxiliary blowers
7 Free spares for mounting of bridge control equipment for main engine
8 Switch and lamp for cancelling of limiters for governor
9 Engine control handle, option: 4 65 625 from engine maker
* 10 Pressure gauges for:
   - Scavenge air
   - Lubricating oil, main engine
   - Cooling oil, main engine
   - Jacket cooling water
   - Sea cooling water
   - Lubricating oil, camshaft
   - Fuel oil before filter
   - Fuel oil after filter
   - Starting air
   - Control air supply
* 10 Thermometer:
   - Jacket cooling water
   - Lubricating oil water

Note: If an axial vibration monitor is ordered (option: 4 31 116) the manoeuvring console has to be extended by a remote alarm/slow down indication lamp.

* These instruments have to be ordered as option: 4 75 645 and the corresponding analogue sensors on the engine as option: 4 75 128.

Engine Control System Interface to Surrounding Systems

To support the navigator, the vessels are equipped with a ship control system, which includes subsystems to supervise and protect the main propulsion engine.

The monitoring systems and instrumentation are explained in detail in Chapter 18.

**Alarm system**

The alarm system has no direct effect on the Engine Control System (ECS). The alarm alerts the operator of an abnormal condition.

The alarm system is an independent system, in general covering more than the main engine itself, and its task is to monitor the service condition and to activate the alarms if a normal service limit is exceeded.

The signals from the alarm sensors can be used for the slow down function as well as for remote indication.

**Slow down system**

The engine safety system is an independent system with its respective sensors on the main engine, fulfilling the requirements of the respective classification society and MAN Diesel & Turbo.

**Safety system**

The engine safety system is an independent system with its respective sensors on the main engine, fulfilling the requirements of the respective classification society and MAN Diesel & Turbo.

If a critical value is reached for one of the measuring points, the input signal from the safety system must cause either a cancellable or a non-cancellable shut down signal to the ECS.

The safety system is included as standard in the extent of delivery.

For the safety system, combined shut down and slow down panels approved by MAN Diesel & Turbo are available. The following options are listed in the Extent of Delivery:

4 75 631 Lyngsø Marine
4 75 632 Kongsberg Maritime
4 75 633 Nabtesco
4 75 636 Mitsui Zosen Systems Research.

Where separate shut down and slow down panels are installed only panels approved by MAN Diesel & Turbo must be used.

In any case, the remote control system and the safety system (shut down and slow down panel) must be compatible.

**Telegraph system**

The telegraph system is an independent system.

This system enables the navigator to transfer the commands of engine speed and direction of rotation from the Bridge, the engine control room or the Engine Side Console (ESC).

**Remote Control system**

The remote control system normally has two alternative control stations:

- the Bridge Control console
- the Engine Control Room console

The remote control system is to be delivered by a supplier approved by MAN Diesel & Turbo.
Bridge control systems from suppliers approved by MAN Diesel & Turbo are available. The Extent of Delivery lists the following options:

- for Fixed Pitch propeller plants, e.g.:
  - 4 95 601 Lyngsø Marine
  - 4 95 607 Nabtesco
  - 4 95 608 Mitsui Zosen Systems Research
  - 4 95 615 Kongsberg Maritime

- and for Controllable Pitch propeller plants, e.g.:
  - 4 95 604 Lyngsø Marine
  - 4 95 916 Kongsberg Maritime
  - 4 95 619 MAN Alphatronic.

**Power Management system**

The system handles the supply of electrical power onboard, i.e. the starting and stopping of the generating sets as well as the activation / deactivation of the main engine Shaft Generator (SG), if fitted.

The normal function involves starting, synchronising, phasing-in, transfer of electrical load and stopping of the generators based on the electrical load of the grid on board.

The activation / deactivation of the SG is to be done within the engine speed range which fulfils the specified limits of the electrical frequency.

**Auxiliary equipment system**

The input signals for ‘Auxiliary system ready’ are given partly based on the status for:

- fuel oil system
- lube oil system
- cooling water systems

and partly from the ECS itself:

- turning gear disengaged
- main starting valve in ‘service position’
- control air valve for air spring ‘open’
- auxiliary blowers running
- control air valve ‘open’
- safety air valve ‘open’
- governor ‘in control’
- valve for starting air distributor ‘open’.

**Engine monitoring**

In order to assist the engineer in running the diesel engine at its optimum performance, a MAN Diesel & Turbo’s PMI system, type PT/S off-line or on-line could be applied as an option.

The MAN Diesel & Turbo’s PMI system, type PT/S off-line monitors engine parameters such as:

- cylinder pressure
- fuel oil injection pressure
- scavenge air pressure
- engine speed.

This and other engine monitoring systems are further explained in Chapter 18 in this Project Guide.

**Instrumentation**

Chapter 18 includes lists of instrumentation for:

- The CoCos-EDS on-line system
- The class requirements and MAN Diesel & Turbo's requirements for alarms, slow down and shut down for Unattended Machinery Spaces.
Vibration Aspects

The vibration characteristics of the two-stroke low speed diesel engines can for practical purposes be split up into four categories, and if the adequate countermeasures are considered from the early project stage, the influence of the excitation sources can be minimised or fully compensated.

In general, the marine diesel engine may influence the hull with the following:

- **External unbalanced moments**
  These can be classified as unbalanced 1st and 2nd order external moments, which need to be considered only for certain cylinder numbers

- **Guide force moments**

- **Axial vibrations in the shaft system**

- **Torsional vibrations in the shaft system**

The external unbalanced moments and guide force moments are illustrated in Fig. 17.01.01.

In the following, a brief description is given of their origin and of the proper countermeasures needed to render them harmless.

**External unbalanced moments**

The inertia forces originating from the unbalanced rotating and reciprocating masses of the engine create unbalanced external moments although the external forces are zero.

Of these moments, the 1st order (one cycle per revolution) and the 2nd order (two cycles per revolution) need to be considered for engines with a low number of cylinders. On 7-cylinder engines, also the 4th order external moment may have to be examined. The inertia forces on engines with more than 6 cylinders tend, more or less, to neutralise themselves.

Countermeasures have to be taken if hull resonance occurs in the operating speed range, and if the vibration level leads to higher accelerations and/or velocities than the guidance values given by international standards or recommendations (for instance related to special agreement between shipowner and shipyard). The natural frequency of the hull depends on the hull’s rigidity and distribution of masses, whereas the vibration level at resonance depends mainly on the magnitude of the external moment and the engine’s position in relation to the vibration nodes of the ship.

**Fig. 17.01.01: External unbalanced moments and guide force moments**

- A – Combustion pressure
- B – Guide force
- C – Staybolt force
- D – Main bearing force

1st order moment vertical 1 cycle/rev.
2nd order moment, vertical 2 cycle/rev.

1st order moment, horizontal 1 cycle/rev.

Z is 1 or 2 times number of cylinder

Z = 1, 2, 3 ... 11, 12, 14

178 06 82-8.2
2nd Order Moments on 4, 5 and 6-cylinder Engines

The 2nd order moment acts only in the vertical direction. Precautions need only to be considered for 4, 5 and 6-cylinder engines in general.

Resonance with the 2nd order moment may occur in the event of hull vibrations with more than 3 nodes. Contrary to the calculation of natural frequency with 2 and 3 nodes, the calculation of the 4 and 5-node natural frequencies for the hull is a rather comprehensive procedure and often not very accurate, despite advanced calculation methods.

A 2nd order moment compensator comprises two counter-rotating masses running at twice the engine speed.

Compensator solutions

Several solutions are available to cope with the 2nd order moment, as shown in Fig. 17.03.02, out of which the most cost efficient one can be chosen in the individual case, e.g.:

1) No compensators, if considered unnecessary on the basis of natural frequency, nodal point and size of the 2nd order moment.

2) A compensator mounted on the aft end of the engine, driven by the main chain drive, option: 4 31 203.

3) A compensator mounted on the fore end, driven from the crankshaft through a separate chain drive, option: 4 31 213.

4) Compensators on both aft and fore ends, driven from the crankshaft by the main chain drive and a separate chain drive respectively, options: 4 31 203 and 4 31 213.

As standard, the compensators reduce the external 2nd order moment to a level as for a 7-cylinder engine or less.

Briefly speaking, solution 1) is applicable if the node is located far from the engine, or the engine is positioned more or less between nodes. Solution 2) or 3) should be considered where one of the engine ends is positioned in a node or close to it, since a compensator is inefficient in a node or close to it and therefore superfluous. Solution 4) should be considered if the engine is positioned over the node.

Determine the need

A decision regarding the vibrational aspects and the possible use of compensators must be taken at the contract stage. If no experience is available from sister ships, which would be the best basis for deciding whether compensators are necessary or not, it is advisable to make calculations to determine which of the solutions should be applied.
Preparation for compensators

If compensator(s) are initially omitted, the engine can be delivered prepared for compensators to be fitted on engine fore end later on, but the decision to prepare or not must be taken at the contract stage, option: 4 31 212 (types 46 only). Measurements taken during the sea trial, or later in service and with fully loaded ship, will be able to show if compensator(s) have to be fitted at all.

If no calculations are available at the contract stage, we advise to make preparations for the fitting of a compensator in the steering compartment, see Section 17.03.

Basic design regarding compensators

Experience with our two-stroke slow speed engines has shown that propulsion plants with small bore engines (engines smaller than 46 types) are less sensitive regarding hull vibrations exited by 2nd order moments than the larger bore engines. Therefore, these engines do not have engine driven 2nd order moment compensators.

For 5 and 6-cylinder engines type 46, the basic design regarding 2nd order moment compensators is:

• With compensator aft, EoD: 4 31 203
• Prepared for compensator fore, EoD: 4 31 212

The available options for 5 and 6-cylinder engines are listed in the Extent of Delivery. For 4-cylinder engines, the information is available on request.
1st Order Moments on 4-cylinder Engines

1st order moments act in both vertical and horizontal direction. For our two-stroke engines with standard balancing these are of the same magnitudes.

For engines with five cylinders or more, the 1st order moment is rarely of any significance to the ship. It can, however, be of a disturbing magnitude in four-cylinder engines.

Resonance with a 1st order moment may occur for hull vibrations with 2 and/or 3 nodes. This resonance can be calculated with reasonable accuracy, and the calculation will show whether a compensator is necessary or not on four-cylinder engines.

A resonance with the vertical moment for the 2 node hull vibration can often be critical, whereas the resonance with the horizontal moment occurs at a higher speed than the nominal because of the higher natural frequency of horizontal hull vibrations.

Balancing 1st order moments

As standard, four-cylinder engines are fitted with 1st order moment balancers in shape of adjustable counterweights, as illustrated in Fig. 17.02.02. These can reduce the vertical moment to an insignificant value (although, increasing correspondingly the horizontal moment), so this resonance is easily dealt with. A solution with zero horizontal moment is also available.

1st order moment compensators

In rare cases, where the 1st order moment will cause resonance with both the vertical and the horizontal hull vibration mode in the normal speed range of the engine, a 1st order compensator can be introduced as an option, reducing the 1st order moment to a harmless value.

Since resonance with both the vertical and the horizontal hull vibration mode is rare, the standard engine is not prepared for the fitting of 1st order moment compensators.

Data on 1st order moment compensators and preparation as well as options in the Extent of Delivery are available on request.

Fig. 17.02.02: Examples of counterweights
Electrically Driven Moment Compensator

If it is decided not to use chain driven moment compensators and, furthermore, not to prepare the main engine for compensators to be fitted later, another solution can be used, if annoying 2nd order vibrations should occur: An external electrically driven moment compensator can neutralise the excitation, synchronised to the correct phase relative to the external force or moment.

This type of compensator needs an extra seating fitted, preferably, in the steering gear room where vibratory deflections are largest and the effect of the compensator will therefore be greatest.

The electrically driven compensator will not give rise to distorting stresses in the hull, but it is more expensive than the engine-mounted compensators. It does, however, offer several advantages over the engine mounted solutions:

- When placed in the steering gear room, the compensator is not as sensitive to the positioning of the node as the compensators 2) and 3) mentioned in Section 17.02.
- The decision whether or not to install compensators can be taken at a much later stage of a project, since no special version of the engine structure has to be ordered for the installation.
- No preparation for a later installation nor an extra chain drive for the compensator on the fore end of the engine is required. This saves the cost of such preparation, often left unused.
- Compensators could be retrofit, even on ships in service, and also be applied to engines with a higher number of cylinders than is normally considered relevant, if found necessary.
- The compensator only needs to be active at speeds critical for the hull girder vibration. Thus, it may be activated or deactivated at specified speeds automatically or manually.
- Combinations with and without moment compensators are not required in torsional and axial vibration calculations, since the electrically driven moment compensator is not part of the mass-elastic system of the crankshaft.

Furthermore, by using the compensator as a vibration exciter a ship’s vibration pattern can easily be identified without having the engine running, e.g. on newbuildings at an advanced stage of construction. If it is verified that a ship does not need the compensator, it can be removed and reused on another ship.

It is a condition for the application of the rotating force moment compensator that no annoying longitudinal hull girder vibration modes are excited. Based on our present knowledge, and confirmed by actual vibration measurements onboard a ship, we do not expect such problems.

Balancing other forces and moments

Further to compensating 2nd order moments, electrically driven balancers are also available for balancing other forces and moments. The available options are listed in the Extent of Delivery.
Moment compensator
Fore end, option: 4 31 213

Moment compensator
Aft end, option: 4 31 203

Compensating moment
$F_{2C} \times L_{node}$
outbalances $M_{2V}$

Moment from compensator
$M_{2C}$ reduces $M_{2V}$

Electrically driven moment compensator
Compensating moment
$F_D \times L_{node}$
outbalances $M_{2V}$

3 and 4-node vertical hull girder mode

Fig. 17.03.02: Compensation of 2nd order vertical external moments
Power Related Unbalance

To evaluate if there is a risk that 1st and 2nd order external moments will excite disturbing hull vibrations, the concept Power Related Unbalance (PRU) can be used as a guidance, see Table 17.04.01 below.

\[
PRU = \frac{\text{External moment}}{\text{Engine power}} \text{ Nm/kW}
\]

With the PRU-value, stating the external moment relative to the engine power, it is possible to give an estimate of the risk of hull vibrations for a specific engine.

Based on service experience from a great number of large ships with engines of different types and cylinder numbers, the PRU-values have been classified in four groups as follows:

<table>
<thead>
<tr>

Based on external moments in layout point L,

N.a. Not applicable

*Table 17.04.01: Power Related Unbalance (PRU) values in Nm/kW*

**Calculation of External Moments**

In the table at the end of this chapter, the external moments \( M_A \) are stated at the speed \( n_i \) and MCR rating in point L_i of the layout diagram. For other speeds \( n_j \), the corresponding external moments \( M_A \) are calculated by means of the formula:

\[
M_A = M_i \times \left( \frac{n_j}{n_i} \right)^2 \text{ kNm}
\]

(The tolerance on the calculated values is 2.5%).
Guide Force Moments

The so-called guide force moments are caused by the transverse reaction forces acting on the crossheads due to the connecting rod/crankshaft mechanism. These moments may excite engine vibrations, moving the engine top athwartships and causing a rocking (excited by H-moment) or twisting (excited by X-moment) movement of the engine as illustrated in Fig. 17.05.01.

The guide force moments corresponding to the MCR rating ($L_1$) are stated in Table 17.07.01.

Top bracing

The guide force moments are harmless except when resonance vibrations occur in the engine/double bottom system.

As this system is very difficult to calculate with the necessary accuracy, MAN Diesel & Turbo strongly recommend, as standard, that top bracing is installed between the engine's upper platform brackets and the casing side.

The vibration level on the engine when installed in the vessel must comply with MAN Diesel & Turbo vibration limits as stated in Fig. 17.05.02.

We recommend using the hydraulic top bracing which allow adjustment to the loading conditions of the ship. Mechanical top bracings with stiff connections are available on request.

With both types of top bracing, the above-mentioned natural frequency will increase to a level where resonance will occur above the normal engine speed. Details of the top bracings are shown in Chapter 05.

Definition of Guide Force Moments

Over the years it has been discussed how to define the guide force moments. Especially now that complete FEM-models are made to predict hull/engine interaction, the proper definition of these moments has become increasingly important.

H-type Guide Force Moment ($M_H$)

Each cylinder unit produces a force couple consisting of:
1. A force at crankshaft level
2. Another force at crosshead guide level. The position of the force changes over one revolution as the guide shoe reciprocates on the guide.

![Fig. 17.05.01: H-type and X-type guide force moments](image-url)
As the deflection shape for the H-type is equal for each cylinder, the Nth order H-type guide force moment for an N-cylinder engine with regular firing order is:

$$N \times M_{H\text{cylinder}}$$

For modelling purposes, the size of the forces in the force couple is:

$$\text{Force} = M_{H}/L \text{ [kN]}$$

where L is the distance between crankshaft level and the middle position of the crosshead guide (i.e. the length of the connecting rod).

As the interaction between engine and hull is at the engine seating and the top bracing positions, this force couple may alternatively be applied in those positions with a vertical distance of (Lz). Then the force can be calculated as:

$$\text{Force}_{z} = M_{H}/L_{z} \text{ [kN]}$$

Any other vertical distance may be applied so as to accommodate the actual hull (FEM) model.

The force couple may be distributed at any number of points in the longitudinal direction. A reasonable way of dividing the couple is by the number of top bracing and then applying the forces at those points:

$$\text{Force}_{z, \text{one point}} = \text{Force}_{z, \text{total}}/N_{\text{top bracing, total}} \text{ [kN]}$$

**X-type Guide Force Moment (M_X)**

The X-type guide force moment is calculated based on the same force couple as described above. However, as the deflection shape is twisting the engine, each cylinder unit does not contribute with an equal amount. The centre units do not contribute very much whereas the units at each end contribute much.

A so-called ‘Bi-moment’ can be calculated (Fig. 17.05.01):

‘Bi-moment’ = \(\sum \text{[force-couple(cyl.X)] \times distX}\) in kNm²

The X-type guide force moment is then defined as:

$$M_{X} = \text{‘Bi-Moment’}/L \text{ kNm}$$

For modelling purpose, the size of the four (4) forces can be calculated:

$$\text{Force} = M_{X}/L_{X} \text{ [kN]}$$

where:

$$L_{X}$$ is the horizontal length between ‘force points’.

Similar to the situation for the H-type guide force moment, the forces may be applied in positions suitable for the FEM model of the hull. Thus the forces may be referred to another vertical level Lz above the crankshaft centre line. These forces can be calculated as follows:

$$\text{Force}_{z, \text{one point}} = \frac{M_{X} \times L}{L_{z} \times L_{X}} \text{ [kN]}$$

In order to calculate the forces, it is necessary to know the lengths of the connecting rods = L, which are:

Vibration Limits Valid for Single Order Harmonics

Zone I: Acceptable
Zone II: Vibration will not damage the main engine, however, under adverse conditions, annoying/harmful vibration responses may appear in the connected structures
Zone III: Not acceptable

Fig.17.05.02: Vibration limits
Axial Vibrations

When the crank throw is loaded by the gas pressure through the connecting rod mechanism, the arms of the crank throw deflect in the axial direction of the crankshaft, exciting axial vibrations. Through the thrust bearing, the system is connected to the ship’s hull.

Generally, only zero-node axial vibrations are of interest. Thus the effect of the additional bending stresses in the crankshaft and possible vibrations of the ship’s structure due to the reaction force in the thrust bearing are to be considered.

An axial damper is fitted as standard on all engines, minimising the effects of the axial vibrations, EcD: 4 31 111.

Torsional Vibrations

The reciprocating and rotating masses of the engine including the crankshaft, the thrust shaft, the intermediate shaft(s), the propeller shaft and the propeller are for calculation purposes considered a system of rotating masses (inertias) interconnected by torsional springs. The gas pressure of the engine acts through the connecting rod mechanism with a varying torque on each crank throw, exciting torsional vibration in the system with different frequencies.

In general, only torsional vibrations with one and two nodes need to be considered. The main critical order, causing the largest extra stresses in the shaft line, is normally the vibration with order equal to the number of cylinders, i.e., six cycles per revolution on a six cylinder engine. This resonance is positioned at the engine speed corresponding to the natural torsional frequency divided by the number of cylinders.

The torsional vibration conditions may, for certain installations require a torsional vibration damper, option: 4 31 105.

Plants with 11 or 12-cylinder engines type 98-80 require a torsional vibration damper.

Based on our statistics, this need may arise for the following types of installation:
- Plants with controllable pitch propeller
- Plants with unusual shafting layout and for special owner/yard requirements
- Plants with 8-cylinder engines.

Undercritical running

The natural frequency of the one-node vibration is so adjusted that resonance with the main critical order occurs about 35-45% above the engine speed at specified MCR.

Such undercritical conditions can be realised by choosing a rigid shaft system, leading to a relatively high natural frequency.

The characteristics of an undercritical system are normally:
- Relatively short shafting system
- Probably no tuning wheel
- Turning wheel with relatively low inertia
- Large diameters of shafting, enabling the use of shafting material with a moderate ultimate tensile strength, but requiring careful shaft alignment, (due to relatively high bending stiffness)
- Without barred speed range.

The so-called QPT (Quick Passage of a barred speed range Technique), is an alternative to a torsional vibration damper, on a plant equipped with a controllable pitch propeller. The QPT could be implemented in the governor in order to limit the vibratory stresses during the passage of the barred speed range.

The application of the QPT, option: 4 31 108, has to be decided by the engine maker and MAN Diesel & Turbo based on final torsional vibration calculations.

Six-cylinder engines, require special attention. On account of the heavy excitation, the natural frequency of the system with one-node vibration should be situated away from the normal operating speed range, to avoid its effect. This can be achieved by changing the masses and/or the stiffness of the system so as to give a much higher, or much lower, natural frequency, called undercritical or overcritical running, respectively.

Owing to the very large variety of possible shafting arrangements that may be used in combination with a specific engine, only detailed torsional vibration calculations of the specific plant can determine whether or not a torsional vibration damper is necessary.
Critical Running

When running undercritical, significant varying torque at MCR conditions of about 100-150% of the mean torque is to be expected.

This torque (propeller torsional amplitude) induces a significant varying propeller thrust which, under adverse conditions, might excite annoying longitudinal vibrations on engine/double bottom and/or deck house.

The yard should be aware of this and ensure that the complete aft body structure of the ship, including the double bottom in the engine room, is designed to be able to cope with the described phenomena.

Overcritical running

The natural frequency of the one-node vibration is so adjusted that resonance with the main critical order occurs about 30-70% below the engine speed at specified MCR. Such overcritical conditions can be realised by choosing an elastic shaft system, leading to a relatively low natural frequency.

The characteristics of overcritical conditions are:

- Tuning wheel may be necessary on crankshaft fore end
- Turning wheel with relatively high inertia
- Shafts with relatively small diameters, requiring shafting material with a relatively high ultimate tensile strength
- With barred speed range, EoD: 4 07 015, of about ±10% with respect to the critical engine speed.

Torsional vibrations in overcritical conditions may, in special cases, have to be eliminated by the use of a torsional vibration damper.

Overcritical layout is normally applied for engines with more than four cylinders.

Please note:
*We do not include any tuning wheel or torsional vibration damper in the standard scope of supply, as the proper countermeasure has to be found after torsional vibration calculations for the specific plant, and after the decision has been taken if and where a barred speed range might be acceptable.*

a) 1st order moments are, as standard, balanced so as to obtain equal values for horizontal and vertical moments for all cylinder numbers.

c) 5 and 6-cylinder engines can be fitted with 2nd order moment compensators on the aft and fore end, reducing the 2nd order external moment.

Table 17.07.01
Monitoring Systems and Instrumentation
Monitoring Systems and Instrumentation

Engine monitoring and instrumentation can be enhanced by MAN Diesel & Turbo’s PMI system for measuring cylinder pressure and by the CoCoS-EDS (Computer Controlled Surveillance – Engine Diagnostics System) for engine performance evaluation.

The monitoring system measures the main parameters of the engine and makes an evaluation of the general engine condition, indicating the measures to be taken. This ensures that the engine performance is kept within the prescribed limits throughout the engine’s lifetime.

In its basic design the MC engine instrumentation consists of:

- Engine Control System
- Shut-down sensors, option: 4 75 124
- Sensors for alarm, slow down and remote indication according to the classification society’s and MAN Diesel & Turbo’s requirements for UMS, EoD: 4 75 127, see Section 18.04.

The optional extras are:

- CoCoS-EDS Full version (AMS interface), option: 4 09 660
- PMI Off-line system, option: 4 75 208
- PMI Auto-tuning system, option: 4 75 216.

Sensors for CoCoS can be ordered, if required, as option: 4 75 129. They are listed in Section 18.03.

All instruments are identified by a combination of symbols and a position number as shown in Section 18.07.
PMI System

As an option on the MC engines, the mechanical indicator system can be supported by a pressure analyser system for measurement of the cylinder combustion pressure.

Monitoring of cylinder pressures allows for:
- optimising the engine performance
- optimising the fuel economy
- minimising engine load
- minimising operating cost through condition based maintenance
- complying with emission requirements

Measurements

The cylinder pressure is measured by a high performance piezo-electric pressure transducer, mounted on the indicator valve.

The engine speed signal is obtained from an angle encoder mounted on the crankshaft fore end. Alternatively the signal could be obtained from a trigger arrangement on the aft end of the engine.

The PMI system compensates automatically for the twisting experienced by each section of the crankshaft due to the torque generated at different loads.

Fig. 18.02.01: PMI type PT/S off-line, option: 4 75 208
PMI System, Off-line and On-lineVersions

The PMI system is available in two versions, PT/S off-line and on-line, see Fig. 18.02.01 and 02.

The basic functions of the two different versions are:

- **PT/S Off-line version, option 4 75 208:** The manually operated single transducer is moved from one cylinder to another in order to complete measurements on all cylinders.

- **On-line version, option 4 75 215:** Fixed mounted pressure transducing sensor on each cylinder for continuous measurements, analysis and adjustments.

*Fig. 18.02.02: PMI type on-line, option: 4 75 215*
The Computer Controlled Surveillance system is the family name of the software application products from the MAN Diesel group.

In order to obtain an easier, more versatile and continuous diagnostics system, the Engine Control System and the PMI System is recommended extended by the CoCoS-EDS products.

**CoCoS-EDS features**

The CoCoS-EDS, option: 4 09 660, allows for engine condition monitoring through surveillance of operating states and behaviour of diesel engines.

Primary features are:

- Data and trend logging
- Engine performance monitoring, analysis and reporting
- Troubleshooting and diagnostics.

The CoCoS-EDS assists the operator effectively in maintaining the main as well as the auxiliary engines in optimal operating condition.

With CoCoS-EDS, early intervention as well as preventive maintenance, the engine operators are able to reduce the risk of damages and failures. CoCoS-EDS further allow for easier troubleshooting in case of unusual engine behaviour.

**Connectivity**

In order to obtain an easier, more versatile and continuous diagnostics system, the CoCoS-EDS is recommended extended by interfaces to the PMI system and the plant’s alarm and monitoring system.

Table 18.03.01 lists the sensors required to enable online diagnostics for CoCoS-EDS, option: 4 75 129.
## CoCoS-EDS Sensor List

Sensors required for the CoCoS-EDS online engine performance analysis, option: 4 75 129, see Table 18.03.01. All pressure gauges are measuring relative pressure, except for ‘PT 8802 Ambient pressure’.

1) Signal acquired from the Alarm Monitoring System
2) In case of MAN Diesel PMI system: signal from PMI system. Other MIP systems: signal from manual input
3) Resolution of signals transferred to CoCoS-EDS (from the Alarm Monitoring System).

---

**Table 18.03.01: List of sensors for CoCoS-EDS**

---
Alarm – Slow Down and Shut Down System

The shut down system must be electrically sepa-
rated from other systems by using independent
sensors, or sensors common to the alarm system
and the monitoring system but with galvanically
separated electrical circuits, i.e. one sensor with
two sets of electrically independent terminals. The
list of sensors are shown in Table 18.04.04.

The number and position of the terminal boxes
depends on the degree of dismantling specified in
the Dispatch Pattern for the transportation of the
engine based on the lifting capacities available at
the engine maker and at the yard.

Basic safety system design and supply

The basic safety sensors for a MAN B&W engine
are designed for Unattended Machinery Space
(UMS) and comprises:

• the temperature sensors and pressure sensors
  that are specified in the ‘MAN Diesel’ column for
  shut down in Table 18.04.04.

These sensors are included in the basic Extent of
Delivery, EoD: 4 75 124.

Alarm and slow down system design and supply

The basic alarm and slow down sensors for a
MAN B&W engine are designed for Unattended
Machinery Space (UMS) and comprises:

• the sensors for alarm and slow down.

These sensors are included in the basic Extent of
Delivery, EoD: 4 75 127.

The shut down and slow down panels can be or-
dered as options: 4 75 630, 4 75 614 or 4 75 615
whereas the alarm panel is yard’s supply, as it
normally includes several other alarms than those
for the main engine.

For practical reasons, the sensors for the engine
itself are normally delivered from the engine sup-
plier, so they can be wired to terminal boxes on
the engine.

Alarm, slow down and remote indication sensors

The International Association of Classification So-
cieties (IACS) indicates that a common sensor can
be used for alarm, slow down and remote indica-
tion.

A general view of the alarm, slow down and shut
down systems is shown in Fig. 18.04.01.

Tables 18.04.02 and 18.04.03 show the require-
ments by MAN Diesel & Turbo for alarm and slow
down and for UMS by the classification societies
(Class), as well as IACS’ recommendations.

The number of sensors to be applied to a specific
plant is the sum of requirements of the classifica-
tion society, the Buyer and MAN Diesel & Turbo.

If further analogue sensors are required, they can
be ordered as option: 4 75 128.

Slow down functions

The slow down functions are designed to safe-
guard the engine components against overloading
during normal service conditions and to keep the
ship manoeuvrable if fault conditions occur.

The slow down sequence must be adapted to the
actual plant parameters, such as for FPP or CPP,
engine with or without shaft generator, and to the
required operating mode.
**Electrical System, General Outline**

The figure shows the concept approved by all classification societies.

The shut down panel and slow down panel can be combined for some makers.

The classification societies permit having common sensors for slow down, alarm and remote indication.

One common power supply might be used, instead of the three indicated, provided that the systems are equipped with separate fuses.

Other Alarm Functions

Drain Box for Fuel Oil Leakage Alarm

Any leakage from the fuel oil high pressure pipes of any cylinder is drained to a common drain box fitted with a level alarm. This is included in the basic design of MAN B&W engines.

Bearing Condition Monitoring

Based on our experience, we decided in 1990 that all plants must include an oil mist detector specified by MAN Diesel & Turbo. Since then an Oil Mist Detector (OMD) and optionally some extent of Bearing Temperature Monitoring (BTM) equipment have made up the warning arrangements for prevention of crankcase explosions on two-stroke engines. Both warning systems are approved by the classification societies.

In order to achieve a response to damage faster than possible with Oil Mist Detection and Bearing Temperature Monitoring alone we introduce Bearing Wear Monitoring (BWM) systems. By monitoring the actual bearing wear continuously, mechanical damage to the crank-train bearings (main-, crank- and crosshead bearings) can be predicted in time to react and avoid damaging the journal and bearing housing.

If the oil supply to a main bearing fails, the bearing temperature will rise and in such a case a Bearing Temperature Monitoring system will trigger an alarm before wear actually takes place. For that reason the ultimate protection against severe bearing damage and the optimum way of providing early warning, is a combined bearing wear and temperature monitoring system.

For all types of error situations detected by the different bearing condition monitoring systems applies that in addition to damaging the components, in extreme cases, a risk of a crankcase explosion exists.

Oil Mist Detector

The oil mist detector system constantly measures samples of the atmosphere in the crankcase compartments and registers the results on an optical measuring track, where the opacity (degree of haziness) is compared with the opacity of the atmospheric air. If an increased difference is recorded, a slow down is activated (a shut down in case of Germanischer Lloyd).

Furthermore, for shop trials only MAN Diesel & Turbo requires that the oil mist detector is connected to the shut down system.

For personnel safety, the oil mist detectors and related equipment are located on the manoeuvring side of the engine.

The following oil mist detectors are available:

<table>

Bearing Wear Monitoring System

The Bearing Wear Monitoring (BWM) system monitors all three principal crank-train bearings using two proximity sensors forward/aft per cylinder unit and placed inside the frame box.

Targeting the guide shoe bottom ends continuously, the sensors measure the distance to the crosshead in Bottom Dead Center (BDC). Signals are computed and digitally presented to computer hardware, from which a useable and easily interpretable interface is presented to the user.

The measuring precision is more than adequate to obtain an alarm well before steel-to-steel contact in the bearings occur. Also the long-term stability of the measurements has shown to be excellent.

In fact, BWM is expected to provide long-term wear data at better precision and reliability than the manual vertical clearance measurements normally performed by the crew during regular service checks.

For the above reasons, we consider unscheduled open-up inspections of the crank-train bearings to be superfluous, given BWM has been installed.

Two BWM ‘high wear’ alarm levels including deviation alarm apply. The first level of the high wear / deviation alarm is indicated in the alarm panel only while the second level also activates a slow down.

The Extent of Delivery lists four Bearing Wear Monitoring options of which the two systems from Dr. E. Horn and Kongsberg Maritime could also include Bearing Temperature Monitoring:

<table>

<td>Rovsing Dynamics</td>
</tr>
</tbody>
</table>

All types MC-C engines and K98MC are as standard specified with Bearing Wear Monitoring for which any of the mentioned options could be chosen.

Bearing Temperature Monitoring System

The Bearing Temperature Monitoring (BTM) system continuously monitors the temperature of the bearing. Some systems measure the temperature on the backside of the bearing shell directly, other systems detect it by sampling a small part of the return oil from each bearing in the crankcase.

In case a specified temperature is recorded, either a bearing shell/housing temperature or bearing oil outlet temperature alarm is triggered.

In main bearings, the shell/housing temperature or the oil outlet temperature is monitored depending on how the temperature sensor of the BTM system, option: 4 75 133, is installed.

In crankpin and crosshead bearings, the shell/housing temperature or the oil outlet temperature is monitored depending on which BTM system is installed, options: 4 75 134 or 4 75 135.

For shell/housing temperature in main, crankpin and crosshead bearings two high temperature alarm levels apply. The first level alarm is indicated in the alarm panel while the second level activates a slow down.

For oil outlet temperature in main, crankpin and crosshead bearings two high temperature alarm levels including deviation alarm apply. The first level of the high temperature / deviation alarm is indicated in the alarm panel while the second level activates a slow down.

In the Extent of Delivery, there are three options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 75 133</td>
<td>Temperature sensors fitted to main bearings</td>
</tr>
<tr>
<td>4 75 134</td>

</tr>
<tr>
<td>4 75 135</td>
<td>Temperature sensors fitted to main bearings, crankpin bearings and crosshead bearings</td>
</tr>
</tbody>
</table>

S40MC-C9, S35MC-C9 as well as S42MC7, S35MC7, L35MC6 and S26MC6 engines are as standard specified with option 4 75 133.
**Water In Oil Monitoring System**

All MAN B&W types MC-C engines as well as K98MC6/7, S42MC7, L35MC6 and S26MC6 are as standard specified with Water In Oil monitoring system in order to detect and avoid free water in the lubricating oil.

In case the lubricating oil becomes contaminated with an amount of water exceeding our limit of 50% of the saturation point (corresponding to approx. 0.2% water content), acute corrosive wear of the crosshead bearing overlayer may occur. The higher the water content, the faster the wear rate.

To prevent water from accumulating in the lube oil and, thereby, causing damage to the bearings, the oil should be monitored manually or automatically by means of a Water In Oil (WIO) monitoring system connected to the engine alarm and monitoring system. In case of water contamination the source should be found and the equipment inspected and repaired accordingly.

The saturation point of the water content in the lubricating oil varies depending on the age of the lubricating oil, the degree of contamination and the temperature. For this reason, we have chosen to specify the water activity measuring principle and the aw-type sensor. Among the available methods of measuring the water content in the lubricating oil, only the aw-type sensor measures the relationship between the water content and the saturation point regardless of the properties of the lubricating oil.

WIO systems with aw-type sensor measure water activity expressed in ‘aw’ on a scale from 0 to 1. Here, ‘0’ indicates oil totally free of water and ‘1’ oil fully saturated by water.

Alarm levels are specified as follows:

<table>
<thead>
<tr>
<th>Engine condition</th>
<th>Water activity, aw</th>
</tr>
</thead>
<tbody>
<tr>
<td>High alarm level</td>
<td>0.5</td>
</tr>
<tr>
<td>High High alarm level</td>
<td>0.9</td>
</tr>
</tbody>
</table>

The aw = 0.5 alarm level gives sufficient margin to the saturation point in order to avoid free water in the lubricating oil. If the aw = 0.9 alarm level is reached within a short time after the aw = 0.5 alarm, this may be an indication of a water leak into the lubricating oil system.

Please note: Corrosion of the overlayer is a potential problem only for crosshead bearings, because only crosshead bearings are designed with an overlayer. Main, thrust and crankpin bearings may also suffer irreparable damage from water contamination, but the damage mechanism would be different and not as acute.

**Liner Wall Monitoring System**

The Liner Wall Monitoring (LWM) system monitors the temperature of each cylinder liner. It is to be regarded as a tool providing the engine room crew the possibility to react with appropriate countermeasures in case the cylinder oil film is indicating early signs of breakdown.

In doing so, the LWM system can assist the crew in the recognition phase and help avoid consequential scuffing of the cylinder liner and piston rings.

Signs of oil film breakdown in a cylinder liner will appear by way of increased and fluctuating temperatures. Therefore, recording a preset max allowable absolute temperature for the individual cylinder or a max allowed deviation from a calculated average of all sensors will trigger a cylinder liner temperature alarm.

The LWM system includes two sensors placed in the manoeuvring and exhaust side of the liners, near the piston skirt TDC position. The sensors are interfaced to the ship alarm system which monitors the liner temperatures.

For each individual engine, the max and deviation alarm levels are optimised by monitoring the temperature level of each sensor during normal service operation and setting the levels accordingly.

The temperature data is logged on a PC for one week at least and preferably for the duration of a round trip for reference of temperature development.

All types 98 and 90 MC-C and MC engines are as standard specified with Liner Wall Monitoring system. For all other engines, the LWM system is available as an option: 4 75 136.
LDCL Cooling Water Monitoring System

This section is not applicable
Control Devices

The control devices mainly include a position switch (ZS) or a position transmitter (ZT) and solenoid valves (ZV) which are listed in Table 18.06.02 below. The sensor identification codes are listed in Table 18.07.01.

Table 18.06.02: Control devices on engine
Identification of Instruments

The instruments and sensors are identified by a position number which is made up of a combination of letters and an identification number.

Measured or indicating variables

First letters:

- **DS**: Density switch
- **DT**: Density transmitter
- **E**: Electrical component
- **FS**: Flow switch
- **FT**: Flow transmitter
- **GT**: Gauging transmitter, index/load transmitter
- **LI**: Level indication, local
- **LS**: Level switch
- **LT**: Level transmitter
- **PDI**: Pressure difference indication, local
- **PDS**: Pressure difference switch
- **PDT**: Pressure difference transmitter
- **PI**: Pressure indication, local
- **PS**: Pressure switch
- **PT**: Pressure transmitter
- **ST**: Speed transmitter
- **TC**: Thermo couple (NiCr-Ni)
- **TE**: Temperature element (Pt 100)
- **TI**: Temperature indication, local
- **TS**: Temperature switch
- **TT**: Temperature transmitter
- **VS**: Viscosity switch
- **VT**: Viscosity transmitter
- **WI**: Vibration indication, local
- **WS**: Vibration switch
- **WT**: Vibration transmitter
- **XC**: Unclassified control
- **XS**: Unclassified switch
- **XT**: Unclassified transmitter
- **ZS**: Position switch (limit switch)
- **ZT**: Position transmitter (proximity sensor)
- **ZV**: Position valve (solenoid valve)

Location of measuring point

Ident. number; first two digits indicate the measurement point and xx the serial number:

- **11xx**: Manoeuvring system
- **12xx**: Hydraulic power supply system (HPS)
- **13xx**: Hydraulic control oil system, separate oil to HPS
- **14xx**: Combustion pressure supervision
- **15xx**: Top bracing pressure, stand alone type
- **16xx**: Exhaust Gas Recirculation (EGR)
- **20xx**: ECS to/from safety system
- **21xx**: ECS to/from remote control system
- **22xx**: ECS to/from alarm system
- **24xx**: ME ECS outputs
- **29xx**: Power supply units to alarm system
- **30xx**: ECS miscellaneous input/output
- **40xx**: Tacho/crankshaft position system
- **41xx**: Engine cylinder components
- **50xx**: VOC, supply system
- **51xx**: VOC, sealing oil system
- **52xx**: VOC, control oil system
- **53xx**: VOC, other related systems
- **54xx**: VOC, engine related components
- **60xx**: GI-ECS to Fuel Gas Supply System (FGSS)
- **61xx**: GI-ECS to Sealing Oil System
- **62xx**: GI-ECS to Control Air System
- **63xx**: GI-ECS to other GI related systems
- **64xx**: GI engine related components
- **66xx**: Selective Catalytic Reduction (SCR) related component. Stand alone
- **80xx**: Fuel oil system
- **81xx**: Lubricating oil system
- **82xx**: Cylinder lubricating oil system
- **83xx**: Stuffing box drain system
- **84xx**: Cooling water systems, e.g. central, sea and jacket cooling water
- **85xx**: Compressed air supply systems, e.g. control and starting air
- **86xx**: Scavenge air system
- **87xx**: Exhaust gas system
- **88xx**: Miscellaneous functions, e.g. axial vibration
- **90xx**: Project specific functions

*Table 18.07.01a: Identification of instruments*
A0xx  Temporary sensors for projects
xxxx-A  Alternative redundant sensors
xxxx-1  Cylinder/turbocharger numbers

ECS: Engine Control System
GI: Gas Injection engine
VOC: Volatile Organic Compound

Functions
Secondary letters:

A  Alarm
C  Control
H  High
I  Indication, remote
L  Low
R  Recording
S  Switching
X  Unclassified function
Y  Slow down
Z  Shut down

Repeated signals
Signals which are repeated, for example measurements for each cylinder or turbocharger, are provided with a suffix number indicating the location, '1' for cylinder 1, etc.

If redundant sensors are applied for the same measuring point, the suffix is a letter: A, B, C, etc.

Examples

TI 8005 indicates a local temperature indication (thermometer) in the fuel oil system.

ZS1112-A[C] and ZS1112-B[C] indicate two redundant position switches in the manoeuvring system, A and B, for control of the main starting air valve position.

PT 85011[ALY] indicates a pressure transmitter located in the control air supply for remote indication, alarm for low pressure and slow down for low pressure.

Table 18.07.01b: Identification of instruments
Dispatch Pattern, Testing, Spares and Tools
Dispatch Pattern, Testing, Spares and Tools

Painting of Main Engine

The painting specification, Section 19.02, indicates the minimum requirements regarding the quality and the dry film thickness of the coats of, as well as the standard colours applied on MAN B&W engines built in accordance with the 'Copenhagen' standard.

Paints according to builder's standard may be used provided they at least fulfil the requirements stated.

Dispatch Pattern

The dispatch patterns are divided into two classes, see Section 19.03:

A: Short distance transportation and short term storage
B: Overseas or long distance transportation or long term storage.

Short distance transportation (A) is limited by a duration of a few days from delivery ex works until installation, or a distance of approximately 1,000 km and short term storage.

The duration from engine delivery until installation must not exceed 8 weeks.

Dismantling of the engine is limited as much as possible.

Overseas or long distance transportation or long term storage require a class B dispatch pattern.

The duration from engine delivery until installation is assumed to be between 8 weeks and maximum 6 months.

Dismantling is effected to a certain degree with the aim of reducing the transportation volume of the individual units to a suitable extent.

Note:

Long term preservation and seaworthy packing are always to be used for class B.

Furthermore, the dispatch patterns are divided into several degrees of dismantling in which ‘1’ comprises the complete or almost complete engine. Other degrees of dismantling can be agreed upon in each case.

When determining the degree of dismantling, consideration should be given to the lifting capacities and number of crane hooks available at the engine maker and, in particular, at the yard (purchaser).

The approximate masses of the sections appear in Section 19.04. The masses can vary up to 10% depending on the design and options chosen.

Lifting tools and lifting instructions are required for all levels of dispatch pattern. The lifting tools, options: 4 12 110 or 4 12 111, are to be specified when ordering and it should be agreed whether the tools are to be returned to the engine maker, option: 4 12 120, or not, option: 4 12 121.

MAN Diesel & Turbo's recommendations for preservation of disassembled / assembled engines are available on request.

Furthermore, it must be considered whether a drying machine, option: 4 12 601, is to be installed during the transportation and/or storage period.

Shop Trials/Delivery Test

Before leaving the engine maker's works, the engine is to be carefully tested on diesel oil in the presence of representatives of the yard, the shipowner and the classification society.

The shop trial test is to be carried out in accordance with the requirements of the relevant classification society, however a minimum as stated in Section 19.05.
MAN Diesel & Turbo’s recommendations for shop trial, quay trial and sea trial are available on request.

In connection with the shop trial test, it is required to perform a pre-certification survey on engine plants with FPP or CPP, options: 4 06 201 Engine test cycle E3 or 4 06 202 Engine test cycle E2 respectively.

Spare Parts

List of spare parts, unrestricted service

The tendency today is for the classification societies to change their rules such that required spare parts are changed into recommended spare parts.

MAN Diesel & Turbo, however, has decided to keep a set of spare parts included in the basic extent of delivery, EoD: 4 87 601, covering the requirements and recommendations of the major classification societies, see Section 19.06.

This amount is to be considered as minimum safety stock for emergency situations.

Additional spare parts recommended by MAN Diesel & Turbo

The above-mentioned set of spare parts can be extended with the ‘Additional Spare Parts Recommended by MAN Diesel & Turbo’, option: 4 87 603, which facilitates maintenance because, in that case, all the components such as gaskets, sealings, etc. required for an overhaul will be readily available, see Section 19.07.

Wearing parts

The consumable spare parts for a certain period are not included in the above mentioned sets, but can be ordered for the first 1, 2, up to 10 years’ service of a new engine, option: 4 87 629.

The wearing parts that, based on our service experience, are estimated to be required, are listed with service hours in Tables 19.08.01 and 19.08.02.

Large spare parts, dimensions and masses

The approximate dimensions and masses of the larger spare parts are indicated in Section 19.09. A complete list will be delivered by the engine maker.

Tools

List of standard tools

The engine is delivered with the necessary special tools for overhauling purposes. The extent, dimensions and masses of the main tools is stated in Section 19.10. A complete list will be delivered by the engine maker.

Tool panels

Most of the tools are arranged on steel plate panels, EoD: 4 88 660, see Section 19.11 ‘Tool Panels’.

It is recommended to place the panels close to the location where the overhaul is to be carried out.

Scavenge air cooler box inside. (Reversing chamber).

Preparation, actual number of coats, film thickness per coat, etc. must be according to the paint manufacturer's specifications.

Air flow reversing chamber inside and outside.

No surface may be left unpainted. Supervision from manufacturer is recommended in the phase of introduction of the paint system.

All paints must be of good quality. Paints according to builder's standard may be used provided they at least fulfil the above requirements.

The data stated are only to be considered as guidelines. Preparation, number of coats, film thickness per coat, etc., must be in accordance with the paint manufacturer’s specifications.

Fig. 19.02.01: Painting of main engine, option: 4 81 101, 4 81 102 or 4 81 103
Dispatch Pattern

The relevant engine supplier is responsible for the actual execution and delivery extent. As differences may appear in the individual suppliers’ extent and dispatch variants.

**Class A** (option 4 12 020):
Short distance transportation limited by duration of transportation time within a few days or a distance of approximately 1000 km and short term storage.
Duration from engine delivery to installation must not exceed eight weeks.
Dismantling must be limited.

**Class B** (option 4 12 030):
Overseas and other long distance transportation, as well as long-term storage.
Dismantling is effected to reduce the transport volume to a suitable extent.
Long-term preservation and seaworthy packing must always be used.

**Classes A + B comprise the following basic variants:**

**A1 + B1** (option 4 12 021 + 4 12 031)
- Engine complete, i.e. not disassembled

**A2 + B2** (option 4 12 022 + 4 12 032)
- Top section including cylinder frame complete, cylinder covers complete, scavenge air receiver including cooler box and cooler insert, turbocharger(s), camshaft, piston rods complete and galleries with pipes.
- Bottom section including bedplate complete, frame box complete, connecting rods, turning gear, crankshaft complete and galleries.
- Remaining parts, stay bolts, auxiliary blowers, chains, etc.

*Fig. 19.03.01a: Dispatch pattern, engine with turbocharger on exhaust side (4 59 123)*
A3 + B3 (option 4 12 023 + 4 12 033)
- Top section including cylinder frame complete, cylinder covers complete, scavenger air receiver including cooler box and cooler insert, turbocharger(s), camshaft, piston rods complete and galleries with pipes.
- Frame box section including frame box complete, chain drive connecting rods and galleries.
- Bedplate/crankshaft section including bedplate complete, crankshaft complete with wheels and turning gear.
- Remaining parts, stay bolts, auxiliary blowers, chains, etc.

Fig. 19.03.01b: Dispatch pattern, engine with turbocharger on exhaust side (4 59 123)
A4 + B4 (option 4 12 024 + 4 12 034)
- Top section including cylinder frame complete, cylinder covers complete, camshaft, piston rods complete and galleries with pipes on camshaft side.
- Exhaust receiver with pipes.
- Scavenge air receiver with galleries and pipes.
- Turbocharger.
- Air cooler box with cooler insert.
- Frame box section including frame box complete, chain drive, connecting rods and galleries.
- Crankshaft with wheels.
- Bedplate with pipes and turning gear.
- Remaining parts, stay bolts, auxiliary blowers, chains, etc.

Note!
The engine supplier is responsible for the necessary lifting tools and lifting instructions for transportation purpose to the yard.

The delivery extent of tools, ownership and lending/lease conditions are to be stated in the contract.
Furthermore, it must be stated whether a dehumidifier is to be installed during the transportation and/or storage period.

Furthermore, it must be stated whether a dehumidifier is to be installed during the transportation and/or storage period.

Fig. 19.03.02c: Dispatch pattern, engine with turbocharger on aft end (4 59 121)
Table 19.04.01: Dispatch pattern, list of masses and dimensions for engines with turbocharger aft

The weights stated are for standard engines with semi-built crankshaft with forged throws, crosshead guides integrated in the frame box, and MAN Diesel turbocharger. The final weights are to be confirmed by the engine supplier, as variations in major engine components due to the use of local standards (plate thickness etc.), size of tuning wheel, type of turbocharger and the choice of cast/welded or forged component designs may increase the total weight by up to 10%. All masses and dimensions in the dispatch pattern are therefore approximate and do not include packing and lifting tools.

Note: Some engines are equipped with moment compensator and/or tuning wheel. However, the weights for these components are not included in dispatch pattern.
The weights stated are for standard engines with semi-built crankshaft with forged throws, crosshead guides integrated in the frame box, and MAN Diesel turbocharger. The final weights are to be confirmed by the engine supplier, as variations in major engine components due to the use of local standards (plate thickness etc.), size of tuning wheel, type of turbocharger and the choice of cast/welded or forged component designs may increase the total weight by up to 10 %. Shop Test

Minimum delivery test

The minimum delivery test, EoD: 4 14 001, involves:

• Starting and manoeuvring test at no load
• Load test
  Engine to be started and run up to 50% of specified MCR (M) in 1 hour

Followed by:

• 0.50 hour running at 25% of specified MCR
• 0.50 hour running at 50% of specified MCR
• 0.50 hour running at 75% of specified MCR
• 1.00 hour running at 100% of specified MCR
• 0.50 hour running at 110% of specified MCR

Only for Germanischer Lloyd:

• 0.75 hour running at 110% of specified MCR

Governor tests, etc:

• Governor test
• Minimum speed test
• Overspeed test
• Shut down test
• Starting and reversing test
• Turning gear blocking device test
• Start, stop and reversing from the Local Operating Panel (LOP)

Fuel oil test

Before leaving the factory, the engine is to be carefully tested on diesel oil in the presence of representatives of Yard, Shipowner, Classification Society, and MAN Diesel & Turbo.

At each load change, all temperature and pressure levels etc. should stabilise before taking new engine load readings.

Fuel oil analysis is to be presented.

All tests are to be carried out on diesel or gas oil.

EIAPP certificate

Most marine engines installed on ocean going vessels are required to have an ‘Engine International Air Pollution Prevention’ (EIAPP) Certificate, or similar. Therefore, a pre-certification survey is to be carried out for all engines according to the survey method described in the engine’s NOx Technical File, which is prepared by the engine manufacturer. For MAN B&W engines, the Unified Technical File (UTF) format is recommended.

The EIAPP certificate documents that the specific engine meets the international NOx emission limitations specified in Regulation 13 of MARPOL Annex VI. The basic engine ‘Economy running mode’, EoD: 4 06 200, complies with these limitations.

The pre-certification survey for a ‘Parent’ or an ‘Individual’ engine includes NOx measurements during the delivery test. For ‘Member’ engines, a survey according to the group definition for the engine group is needed. This survey should be based on the delivery test.

The applicable test cycles are:

• E3, marine engine, propeller law for FPP, option: 4 06 201
• E2, marine engine, constant speed for CPP, option: 4 06 202

For further information and options regarding shop test, see Extent of Delivery.
List of Spare Parts, Unrestricted Service

Spare parts are requested by the following Classes only: GL, KR, NK and RS, while just recommended by: ABS and LR, but neither requested nor recommended by: BV, CCS, DNV and RINA.

**Cylinder cover, plate 901 and others**
1 Cylinder cover with fuel, exhaust and starting valves, indicator valve and sealing rings (disassembled).
½ set Studs for 1 cylinder cover

**Piston, plate 902**
1 Piston complete (with cooling pipe), piston rod, piston rings and stuffing box, studs and nuts
1 set Piston rings for 1 cylinder

**Cylinder liner, plate 903**
1 Cylinder liner inclusive of sealing rings and gaskets.

**Cylinder lubricator, plate 903 )**
*Standard Spare parts*
1 set Spares for MAN B&W Alpha lubricator for 1 cyl.
1 Lubricator
2 Feed back sensor, complete
1 Suction filter element for pump station
1 Pressure filter element for pump station
1 Complete sets of O-rings for lubricator (depending on No. of lubricating per cylinder)
1 set Ceramic or sand filled fuses 6.3 x 32 mm, for MCU, BCU & SBU (6 pcs 3A and 3 pcs 12A)
2 LED’s for visual feed back indication
or
1 set LED’s for visual feed back indication

**Connecting rod, and crosshead bearing, plate 904**
1 Telescopic pipe with bushing for 1 cylinder
1 Crankpin bearing shells in 2/2 with studs and nuts
1 Crosshead bearing shell lower part with studs and nuts
2 Thrust piece

**Main bearing and thrust block, plate 905**
1 set Thrust pads for one face of each size, if different for ‘ahead’ and ‘astern’

**Chain drive, plate 906 )**
1 Of each type of bearings for camshaft at chain drive, chain tightening and intermediate shaft
6 Camshaft chain links. Only for ABS, LR and NK
1 Mechanically driven cylinder lubricator drive: 6 chain links or gear wheels
1 Guide ring 2/2 for camshaft bearing

**Starting valve, plate 907**
1 Starting valve, complete

**Exhaust valve, plate 908**
2 Exhaust valves complete
(The 2nd exhaust valve is mounted in the Cylinder cover complete)
1 Pressure pipe for exhaust valve pipe

**Fuel pump, plate 909**
1 Fuel pump barrel, complete with plunger
1 High-pressure pipe, each type
1 Suction and puncture valve, complete

**Fuel valve, plate 909**
1 set Fuel valves of each size and type fitted, complete with all fittings, for one engine
a) engines with one or two fuel valves: one set of fuel valves for all cylinders on the engine
b) engines with three and more fuel valves per cylinder: two fuel valves complete per cylinder, and a sufficient number of valve parts, excluding the body, to form, with those fitted in the complete valve, a full engine set

**Turbocharger, plate 910**
1 set Maker’s standard spare parts

**Bedplate, plate 912**
1 Main bearing shell in 2/2 of each size
1 set Studs and nuts for 1 main bearing

) MD required spare parts.

Please note: Plate number refers to Instruction Book, Vol. III containing plates with spare parts.

Fig. 19.06.01: List of spare parts, unrestricted service: 4 87 601
**Additional Spares**

Beyond class requirements or recommendation, for easier maintenance and increased security in operation.

**Cylinder cover, section 90101**
- 4 Studs for exhaust valve
- 4 Nuts for exhaust valve
- ½ set O-rings for cooling jacket
- 1 Cooling jacket
- ½ set Sealing between cylinder cover and liner
- 4 Spring housings for fuel valve
  (applicable for 98-50MC/MC-C only)

**Hydraulic tool for cylinder cover, section 901**
- 1 set Hydraulic hoses with protection hoses complete with couplings
- 8 pcs O-rings with backup rings, upper
- 8 pcs O-rings with backup rings, lower

**Piston and piston rod, section 90201**
- 1 box Locking wire, L=63 m
- 5 Piston rings of each kind
- 2 D-rings for piston skirt
- 2 D-rings for piston rod

**Piston rod stuffing box, section 90202**
- 15 Self-locking nuts
- 5 O-rings
- 5 Top scraper rings
- 15 Pack sealing rings
- 10 Cover sealing rings
- 120 Lamellas for scraper rings
- 30 Springs for top scraper and sealing rings
- 20 Springs for scraper rings

**Cylinder frame, section 90301**
- ½ set Studs for cylinder cover for one cylinder
- 1 Bushing

**Cylinder liner and cooling jacket, section 90301**
- 1 Cooling jacket of each kind
- 4 Non return valves
- 1 set O-rings for one cylinder liner
- ½ set Gaskets for cooling water connection
- ½ set O-rings for cooling water pipes
- 1 set Cooling water pipes between liner and cover for one cylinder

**Mechanically driven cylinder lubricator drive, section 90305**
- 1 Coupling
- 3 Discs

**MAN B&W Alpha Cylinder Lubricating System, section 90302**
- 1 set Spares for MAN B&W Alpha lubricator for one cylinder
- 1 Lubricator
- 2 Feed back sensor, complete
- 1 Suction filter element for pump station
- 1 Pressure filter element for pump station
- 1 Complete sets of O-rings for lubricator
  (depending on no. of lubricating per cylinder)
- 6 3A, 3 pcs. 12A ceramic or sand filled fuses
- 2 6.3 x 32 mm, for MCU, BCU & SBU

**LED’s (Light Emitting Diodes) for visual feedback indication**

**Connecting rod and crosshead, section 90401**
- 1 Telescopic pipe
- 2 Thrust piece

**Chain drive and guide bars, section 90601**
- 4 Guide bar
- 1 set Locking plates and lock washers

**Chain tightener, section 90602**
- 2 Locking plates for tightening

**Camshaft, section 90603**
- 1 Exhaust cam (split repair cam if possible)
- 1 Fuel cam (split repair cam if possible)

**Indicator drive, section 90608**
- 1 set Gaskets for indicator valves
- 3 Indicator valves/ cocks complete

**Regulating shaft, section 90618**
- 3 Resilient arm, complete

**Arrangement of engine side console, plate 90621**
- 2 Pull rods

Table 19.07.01a: Additional spare parts beyond class requirements or recommendation, option: 4 87 603
**Main starting valve, section 90702**
1. Repair kit for main actuator
2. Repair kit for main ball valve
3. Repair kit for actuator, slow turning 1)
4. Repair kit for ball valve, slow turning 2)

1) if fitted

**Starting valve, section 90704**
- 2 Locking plates
- 2 Piston
- 2 Spring
- 2 Bushing
  1 set O-ring
  1 Valve spindle

**Exhaust valve, section 90801**
- 1 Exhaust valve spindle
- 1 Exhaust valve seat
  ½ set O-ring exhaust valve/cylinder cover
- 4 Piston rings
  ½ set Guide rings
  ½ set Sealing rings
  ½ set Safety valves
  1 set Gaskets and O-rings for safety valve
  1 Piston complete
  1 Damper piston
  1 set O-rings and sealings between air piston and exhaust valve housing/spindle
  1 Liner for spindle guide
  1 set Gaskets and O-rings for cool. water conn.
  1 Conical ring in 2/2
  1 set O-rings for spindle/air piston
  1 set Non-return valve

**Exhaust valve, section 908**
- 1 Sealing oil control unit

**Valve gear, section 908**
- 3 Filter, complete
- 5 O-rings of each kind

**Valve gear, section 90805**
- 1 Roller guide complete
- 2 Shaft pin for roller
- 2 Bushing for roller
- 4 Discs
- 2 Non return valve
- 4 Piston rings
- 4 Discs for spring
- 2 Springs
- 2 Roller

**Valve gear, details, section 90806**
- 1 High pressure pipe, complete
- 1 set O-rings for high pressure pipes
- 4 Sealing discs

**Cooling water outlet, section 908**
- 2 Ball valve
- 1 Butterfly valve
- 1 Compensator
- 1 set Gaskets for butterfly valve and compensator

**Fuel pump, section 909**
- 1 Top cover
- 1 Plunger/barrel, complete
- 3 Suction valves
- 3 Puncture valves
  ½ set Sealings, O-rings, gaskets and lock washers

**Fuel pump gear, section 909**
- 1 Fuel pump roller guide, complete
- 2 Shaft pin for roller
- 2 Bushings for roller
- 2 Springs
  1 set Sealing
  2 Roller

**Fuel pump gear, details, section 90910**
  ½ set O-rings for lifting tool

**Fuel pump gear, details, section 90904**
- 1 Shock absorber, complete
- 1 set Spring(s)
- 1 set Sealing and wearing rings
- 4 Felt rings

**Fuel pump gear, reversing mechanism, plate 90905**
- 1 Reversing mechanism, complete
- 2 Spare parts set for air cylinder

**Fuel valve, section 90911**
- 1 set Fuel nozzles
  1 set O-rings for fuel valve
  3 Spindle guides, complete
  ½ set Springs
  ½ set Discs, +30 bar
  3 Thrust spindles
  3 Non return valve (if mounted)

**Fuel oil high pressure pipes, section 90914**
- 1 High pressure pipe, complete of each kind
- 1 set O-rings for high pressure pipes

---

Table 19.07.01b: Additional spare parts beyond class requirements or recommendation, option: 4 87 603
Overflow valve, section 90915
1 Overflow valve, complete
1 O-rings of each kind

Scavenge air receiver, section 91002
2 Non-return valves complete
1 Compensator

Exhaust pipes and receiver, section 910
1 Compensator between TC and receiver
2 Compensator between exhaust valve and receiver
1 set Gaskets for each compensator

Auxiliary blower, section 91003
1 set Bearings for electric motor
1 set Shaft sealings
1 set Bearings/belt/sealings for gearbox (only for belt-driven blowers)

Turbocharger, section 91005
1 Spare rotor for one turbocharger, complete with bearing
1 set Spare parts for one turbocharger

Arrangement of safety cap, section 911
1 set Bursting disc

Note:
Section numbers refer to Instruction Book, Vol. III containing plates with spare parts

Table 19.07.01c: Additional spare parts beyond class requirements or recommendation, option: 4 87 603
Wearing Parts

MAN Diesel & Turbo Service Letter SL-509 provides Guiding Overhaul Intervals and expected service life for key engine components. The wearing parts expected to be replaced at the service hours mentioned in the Service Letter are listed in the tables below.

List of Standard Tools for Maintenance

The engine is delivered with all necessary special tools for scheduled maintenance. The extent of the tools is stated below. Most of the tools are arranged on steel plate panels. It is recommended to place them close to the location where the overhaul is to be carried out, see Section 19.11.

All measurements are for guidance only.

Cylinder Cover, MF/SF 21-9010
1 pcs Tool panel incl. lifting chains, grinding mandrels, extractor tools etc.

Cylinder Unit Tools, MF/SF 21-9014
1 pcs Tool panel incl. pressure testing tool, piston ring expander, stuffing box tools, templates etc.
1 pcs Guide ring for piston
1 pcs Lifting tool for piston
1 pcs Support iron for piston
1 pcs Crossbar for cylinder liner, piston
1 pcs Lifting tool for cylinder liner
1 set Measuring tool for cylinder liner
1 set Test equipment for Alpha Lubricator

Cylinder Cover, MF/SF 21-9010
1 pcs Tool panel incl. lifting chains, grinding mandrels, extractor tools etc.

Fuel Oil System Tools, MF/SF 21-9042
1 pcs Tool panel incl. grinding, lifting, adjustment and assembly tools etc.
1 set Fuel valve nozzle tools
1 set Toolbox for fitting of fuel pump seals
1 pcs Probe light
1 pcs Test rig for fuel valve

Turbocharger System Tools, MF/SF 21-9046
1 set Air cooler cleaning tool
1 set Guide rails, air cooler element
1 pcs Compensator, dismantling tool
1 pcs Travelling trolley

Crosshead and Connection Rod Tools, MF/SF 21-9022
1 pcs Tool panel incl. suspension and lifting tools, protection in crankcase etc.
1 pcs Guide shoe extractor

General Tools, MF/SF 21-9058
1 set Pump for hydraulic jacks incl. hydraulic accessories
1 set Set of tackles, trolleys, eye bolts, shackles, wire ropes
1 set Instruments incl. mechanical / digital measuring tools
1 set Hand tools incl. wrenches, pliers and spanners

Crankshaft and Thrust Bearing Tools, MF/SF 21-9026
1 pcs Tool panel incl. lifting, testing and retaining tools etc.
1 pcs Lifting tool for crankshaft
1 pcs Lifting tool for thrust shaft
1 pcs Crossbar for segment stopper
1 set Feeler gauges

Optional Tools, MF/SF 21-9062
1 pcs Collar ring for piston
1 pcs Support for tilting tool
1 pcs Valve seat and spindle grinder
1 pcs Wear ridge milling machine
1 pcs Work table for exhaust valve

Control Gear Tools, MF/SF 21-9030
1 pcs Tool panel incl. pin gauges, chain assembly tools, camshaft tools etc.

Hydraulic Jacks, MF/SF 21-94
It is important to notice, that some jacks are used on different components on the engine, Fig. 19.10.06

Exhaust Valve Tools, MF/SF 21-9038
1 pcs Tool panel incl. grinding-, lifting-, adjustment- and test tools etc.

Mass of the complete set of tools: Approximately 2,171 kg
Fig. 19.10.01: Dimensions and masses of tools

*All measurements are for guidance only*
The tools for air cooler, compensator and the tools for the turbocharger system are to be stored in a storage room e.g. a drawer.

Required space for these tools are approx.: 1,000 x 500 x 300 mm.

Depending on the turbocharger type chosen for the engine, the blanking plates will vary in size from approx. 380 mm in up to 1,180 mm in diameter. Thickness: 10 to 16 mm.

Only engines with two or more turbochargers will be supplied with blanking plates.

Dimensions varies depending on compensator size.

</tbody>
</table>
Example of a box containing hydraulic jacks for connecting rod and end chocks.

The exact design and dimensions will be specified by the engine builder or subsupplier.

However, as a minimum, the boxes must be provided with the following:

- supports
- rigid handles
- rigid locks
- reinforced corners
- be resistant to water and oil
- hydraulic jacks must be secured in the box.

The table indicates the scope and estimated size of boxes for hydraulic jacks.

Hydraulic jacks are often used at different locations, which is why not all fields have been filled in.

Project Support and Documentation
Project Support and Documentation

The selection of the ideal propulsion plant for a specific newbuilding is a comprehensive task. However, as this selection is a key factor for the profitability of the ship, it is of the utmost importance for the end-user that the right choice is made.

MAN Diesel & Turbo is able to provide a wide variety of support for the shipping and shipbuilding industries all over the world.

The knowledge accumulated over many decades by MAN Diesel & Turbo covering such fields as the selection of the best propulsion machinery, optimisation of the engine installation, choice and suitability of a Power Take Off for a specific project, vibration aspects, environmental control etc., is available to shipowners, shipbuilders and ship designers alike.

Part of this information can be found in the following documentation:

- Marine Engine Programme
- Turbocharger Selection
- Installation Drawings
- CEAS - Engine Room Dimensioning
- Project Guides
- Extent of Delivery (EOD)
- Technical Papers

The publications are available at: www.marine.man.eu → 'Two-Stroke'.

Engine Selection Guides

The 'Engine Selection Guides' are intended as a tool to provide assistance at the very initial stage of the project work. The guides give a general view of the MAN B&W two-stroke Programme for MC as well as for ME and ME-B engines and include information on the following subjects:

- Engine data
- Engine layout and load diagrams
  - specific fuel oil consumption
- Turbocharger selection
- Electricity production, including power take off
- Installation aspects
- Auxiliary systems
- Vibration aspects.

After selecting the engine type on the basis of this general information, and after making sure that the engine fits into the ship's design, then a more detailed project can be carried out based on the 'Project Guide' for the specific engine type selected.

Project Guides

For each engine type of MC, ME or ME-B design a 'Project Guide' has been prepared, describing the general technical features of that specific engine type, and also including some optional features and equipment.

The information is general, and some deviations may appear in a final engine documentation, depending on the content specified in the contract and on the individual licensee supplying the engine. The Project Guides comprise an extension of the general information in the Engine Selection Guide, as well as specific information on such subjects as:

- Engine Design
- Engine Layout and Load Diagrams, SFOC
- Turbocharger Selection & Exhaust Gas By-pass
- Electricity Production
- Installation Aspects
- List of Capacities: Pumps, Coolers & Exhaust Gas
- Fuel Oil
- Lubricating Oil
- Cylinder Lubrication
- Piston Rod Stuffing Box Drain Oil
- Central Cooling Water System
- Seawater Cooling
- Starting and Control Air
- Scavenge Air
- Exhaust Gas
- Engine Control System
- Vibration Aspects
- Monitoring Systems and Instrumentation
- Dispatch Pattern, Testing, Spares and Tools
- Project Support and Documentation.
Installation Data Application

Additional customised information can be obtained from MAN Diesel & Turbo as project support. For this purpose, we have developed the CEAS application, by means of which specific calculations can be made during the project stage.

The CEAS application

The CEAS application is found at www.marine.man.eu → 'Two-Stroke' → 'CEAS Engine Calculations'.

On completion of the CEAS application, a report is generated covering the following:

- Main engine room data
- Specified main engine and ratings
- Ambient reference conditions
- Expected SFOC, lube oil consumption, air and exhaust gas data
- Necessary capacities of auxiliary machinery (SMCR)
- Starting air system, engine dimensions, tanks, etc.
- Tables of SFOC and exhaust gas data
- Heat dissipation of engine
- Water condensation separation in air coolers
- Noise – engine room, exhaust gas, structure borne
- Preheating of diesel engine
- Alternative engines and turbochargers, further reading.

Supplementary project data on request

Further to the data generated by the CEAS application, the following data are available on request at the project stage:

- Estimation of ship’s dimensions
- Propeller calculation and power prediction
- Selection of main engine
- Main engines comparison
- Maintenance and spare parts costs of the engine
- Total economy – comparison of engine rooms
- Steam and electrical power – ships’ requirement
- Utilisation of exhaust gas heat
- Utilisation of jacket cooling water heat, fresh water production
- Exhaust gas back pressure
- Layout/load diagrams of engine.

Links to related MAN Diesel & Turbo publications and papers are provided, too.
MAN Diesel & Turbo’s ‘Extent of Delivery’ (EoD) is provided to facilitate negotiations between the yard, the engine maker, consultants and the customer in specifying the scope of supply for a specific project involving MAN B&W two-stroke engines.

We provide four different EoDs:

- **EoD 70-50 MC-C Tier II Engine**
- **EoD 46-35 MC-C Tier II Engines**
- **EoD 98-50 ME/ME-C/ME-C-GI Tier II Engines**
- **EoD 60-30 ME-B Tier II Engines**

These publications are available in print and at: www.marine.man.eu → 'Two-Stroke' → 'Extent of Delivery (EoD)'.

### Basic items and Options

The ‘Extent of Delivery’ (EoD) is the basis for specifying the scope of supply for a specific order.

The list consists of ‘Basic’ and ‘Optional’ items.

The ‘Basic’ items define the simplest engine, designed for unattended machinery space (UMS), without taking into consideration any further requirements from the classification society, the yard, the owner or any specific regulations.

The ‘Options’ are extra items that can be alternatives to the ‘Basic’, or additional items available to fulfill the requirements/functions for a specific project.

### Copenhagen Standard Extent of Delivery

At MAN Diesel & Turbo, Copenhagen, we base our first quotations on a ‘mostly required’ scope of supply. This is the so-called ‘Copenhagen Standard Extent of Delivery’, which is made up by options marked with an asterisk * in the far left column in the EoD.

The Copenhagen Standard Extent of Delivery includes:

- Minimum of alarm sensors recommended by the classification societies and MAN Diesel & Turbo
- Moment compensator for certain numbers of cylinders
- MAN turbochargers
- The basic Engine Control System
- CoCoS-EDS ME Basic (for ME/ME-B/-GI only)
- Spare parts either required or recommended by the classification societies and MAN Diesel & Turbo
- Tools required or recommended by the classification societies and MAN Diesel & Turbo.

MAN Diesel & Turbo licencees may select a different extent of delivery as their standard.

### EoD and the final contract

The filled-in EoD is often used as an integral part of the final contract.

The final and binding extent of delivery of MAN B&W two-stroke engines is to be supplied by our licensee, the engine maker, who should be contacted in order to determine the execution for the actual project.
**Installation Documentation**

When a final contract is signed, a complete set of documentation, in the following called 'Installation Documentation', will be supplied to the buyer by the engine maker.

The extent of Installation Documentation is decided by the engine maker and may vary from order to order.

As an example, for an engine delivered according to MAN Diesel & Turbo's 'Copenhagen Standard Extent of Delivery', the Installation Documentation is divided into the volumes ‘A’ and ‘B’:

- **4 09 602 Volume ‘A’**
  Mainly comprises general guiding system drawings for the engine room

- **4 09 603 Volume ‘B’**
  Mainly comprises specific drawings for the main engine itself.

Most of the documentation in volume ‘A’ are similar to those contained in the respective Project Guides, but the Installation Documentation will only cover the order-relevant designs.

The engine layout drawings in volume ‘B’ will, in each case, be customised according to the buyer’s requirements and the engine maker’s production facilities.

A typical extent of a set of volume ‘A’ and ‘B’ drawings is listed in the following.

For questions concerning the actual extent of Installation Documentation, please contact the engine maker.

**Engine-relevant documentation**

- **Engine data, on engine**
  - External forces and moments
  - Guide force moments
  - Water and oil in engine
  - Centre of gravity
  - Basic symbols for piping
  - Instrument symbols for piping
  - Balancing

- **Engine connections**
  - Engine outline
  - List of flanges/counterflanges
  - Engine pipe connections

- **Engine instrumentation**
  - List of instruments
  - Connections for electric components
  - Guidance values automation, engine
  - Electrical wiring

- **Engine Control System**
  - Engine Control System, description
  - Engine Control System, diagrams
  - Pneumatic system
  - Speed correlation to telegraph
  - List of components
  - Sequence diagram

- **Control equipment for auxiliary blower**
  - Electric wiring diagram
  - Auxiliary blower
  - Starter for electric motors

- **Shaft line, on engine**
  - Crankshaft driving end
  - Fitted bolts

- **Turning gear**
  - Turning gear arrangement
  - Turning gear, control system
  - Turning gear, with motor

- **Spare parts**
  - List of spare parts
**Engine paint**
Specification of paint

**Gaskets, sealings, O-rings**
Instructions
Packings
Gaskets, sealings, O-rings

**Engine pipe diagrams**
Engine pipe diagrams
Bedplate drain pipes
Instrument symbols for piping
Basic symbols for piping
Lubricating oil, cooling oil and hydraulic oil piping
Cylinder lubricating oil pipes
Stuffing box drain pipes
Cooling water pipes, air cooler
Jacket water cooling pipes
Fuel oil drain pipes
Fuel oil pipes
Control air pipes
Starting air pipes
Turbocharger cleaning pipe
Scavenge air space, drain pipes
Scavenge air pipes
Air cooler cleaning pipes
Exhaust gas pipes
Steam extinguishing, in scavenge air box
Oil mist detector pipes, if applicable
Pressure gauge pipes

**Engine room-relevant documentation**

**Engine data, in engine room**
List of capacities
Basic symbols for piping
Instrument symbols for piping

**Lubricating and cooling oil**
Lubricating oil bottom tank
Lubricating oil filter
Crankcase venting
Lubricating and hydraulic oil system
Lubricating oil outlet

**Cylinder lubrication**
Cylinder lubricating oil system

**Piston rod stuffing box**
Stuffing box drain oil cleaning system

**Seawater cooling**
Seawater cooling system

**Jacket water cooling**
Jacket water cooling system
Deaerating tank
Deaerating tank, alarm device

**Central cooling system**
Central cooling water system
Deaerating tank
Deaerating tank, alarm device

**Fuel oil system**
Fuel oil heating chart
Fuel oil system
Fuel oil venting box
Fuel oil filter

**Compressed air**
Starting air system

**Scavenge air**
Scavenge air drain system

**Air cooler cleaning**
Air cooler cleaning system

**Exhaust gas**
Exhaust pipes, bracing
Exhaust pipe system, dimensions
Engine room crane
Engine room crane capacity, overhauling space

Torsiograph arrangement
Torsiograph arrangement

Shaft earthing device
Earthing device

Fire extinguishing in scavenge air space
Fire extinguishing in scavenge air space

Instrumentation
Axial vibration monitor

Engine seating
Profile of engine seating
Epoxy chocks
Alignment screws

Holding-down bolts
Holding-down bolt
Round nut
Distance pipe
Spherical washer
Spherical nut
Assembly of holding-down bolt
Protecting cap
Arrangement of holding-down bolts

Side chocks
Side chocks
Liner for side chocks, starboard
Liner for side chocks, port side

End chocks
Stud for end chock bolt
End chock
Round nut
Spherical washer, concave
Spherical washer, convex
Assembly of end chock bolt
Liner for end chock
Protecting cap

Engine top bracing
Top bracing outline
Top bracing arrangement
Friction-materials
Top bracing instructions
Top bracing forces
Top bracing tension data

Shaft line, in engine room
Static thrust shaft load
Fitted bolt

Power Take-Off
List of capacities
PTO/RCF arrangement, if fitted

Large spare parts, dimensions
Connecting rod studs
Cooling jacket
Crankpin bearing shell
Crosshead bearing
Cylinder cover stud
Cylinder cover
Cylinder liner
Exhaust valve
Exhaust valve bottom piece
Exhaust valve spindle
Exhaust valve studs
Fuel valve
Main bearing shell
Main bearing studs
Piston complete
Starting valve
Telescope pipe
Thrust block segment
Turbocharger rotor

Gaskets, sealings, O-rings
Gaskets, sealings, O-rings

Material sheets
MAN Diesel & Turbo Standard Sheets Nos.:
- S19R
- S45R
- S25Cr1
- S34Cr1R
- C4
**Engine production and installation-relevant documentation**

**Main engine production records, engine installation drawings**
- Installation of engine on board
- Dispatch pattern 1, or
- Dispatch pattern 2
- Check of alignment and bearing clearances
- Optical instrument or laser
- Reference sag line for piano wire
- Alignment of bedplate
- Piano wire measurement of bedplate
- Check of twist of bedplate
- Crankshaft alignment reading
- Bearing clearances
- Check of reciprocating parts
- Production schedule
- Inspection after shop trials
- Dispatch pattern, outline
- Preservation instructions

**Tools**

**Engine tools**
- List of tools
- Outline dimensions, main tools

**Tool panels**
- Tool panels

**Engine seating tools**
- Hydraulic jack for holding down bolts
- Hydraulic jack for end chock bolts

**Auxiliary equipment**
- Ordered auxiliary equipment

**Shop trials**
- Shop trials, delivery test
- Shop trial report

**Quay trial and sea trial**
- Stuffing box drain cleaning
- Fuel oil preheating chart
- Flushing of lubricating oil system
- Freshwater system treatment
- Freshwater system preheating
- Quay trial and sea trial
- Adjustment of control air system
- Adjustment of fuel pump
- Heavy fuel operation
- Guidance values automation

**Flushing procedures**
- Lubricating oil system cleaning instruction
