Dear Sirs

It has come to our attention that MAN B&W marine two-stroke engines equipped with exhaust gas bypass (EGB), turbocharger cut-out (TCCO), variable turbocharger (VT), hybrid turbocharger (TCG), and interface to the vessel’s power management system (PMS) are subject to increased risk of TC overspeed.

For vessels equipped with this specific combination of technologies, we recommend upgrading the safety system’s action when overspeeding of the TC is detected.

Table 1 on page 2 provides an overview of the plant configurations on which shutdown should be implemented if the turbocharger overspeeds.

Yours faithfully

Mikael C Jensen
Vice President, Engineering

Stig B Jakobsen
Senior Manager, Operation
Previously, our recommendation was to initiate slowdown if TC overspeeding was detected on the engine plant configurations described in Table 1. Now, we recommend a shutdown instead.

This change should be implemented in the main engine safety system for these plants.

The reason why these plants are at a higher risk of suffering damage to the TC is that certain configurations enforce a delay before the main engine fuel index is reduced, as opposed to a shutdown which is effective instantly.

This delay is enforced to allow the PMS to distribute the load from the main engine driven generators to other sources. This delay can lead to overspeeding of the turbocharger, as the gas amount to the TC remains unchanged even after a high rpm level is detected by the safety system.

It is important to note that the modification does not concern personal safety, as it is solely a matter of protecting the turbocharger against overspeeding.

Owners of the engine plants concerned can contact our Operation Department for a detailed specification of the safety system functionality.

Questions or comments regarding this SL should be directed to our Operation Department LEO (e-mail: leo@mandieselturbo.com).
